Consumers

III. ENHANCING CONSUMER PRIVACY ONLINE

During the first day of the Workshop, participants discussed enhancing consumer privacy online through technological innovation, education, self-regulation, and law enforcement. They agreed that if consumers are not confident that their personal information will be protected or will not use the Internet for commercial purposes and the online marketplace will not thrive. (1)

A. Technologies to Enhance Notice and Consumer Choice Online

The Workshop highlighted three technologies that, in the view of many participants, could enhance online privacy and at the same time serve legitimate needs of online businesses for information about current or potential customers. The approaches include technology that was the time of the Workshop, as well as technology that could be adapted or extended to enhance notice and consumer choice with respect to information privacy online.

1. Universal Registration Systems

A representative of Internet Profiles Corporation (I/PRO), a market research firm, demonstrated the I/CODE system, a universal World Wide Web registration system. (2) Users and Web sites register with the system. When users register, they provide I/PRO with an array of personal information, including identifying information (name, street address, e-mail address), demographic information (age, gender, marital status), and information about product and service preferences. (3) In return for this information, users receive an identifier called an I/CODE, which allows them to browse anonymously in the Web sites in the I/CODE system. (4) I/PRO aggregates the anonymous demographic information for market analysis. (5)

When a user accesses a site in the I/CODE system, only the user's I/CODE and anonymous demographic information are transmitted to I/PRO. I/PRO uses the anonymous information collected in this manner by the site to perform aggregate data analysis for its clients. In response to a request from the site, the user may opt to disclose his or her e-mail address, in order to receive future communications from the site, and forwards the user's name and street address to the site. Personally identifying information is not sent to the site without the user's consent. (6) All of the personal information transmitted between I/CODE and sites registered in the I/CODE system is encrypted. I/PRO aggregates sites within the I/CODE system are contractually bound not to share or sell collected personal information to entities outside the I/CODE system.

Within the I/CODE system, consumers enjoy a measure of control over how their personally identifying information is used online by registered sites. The system shelters users from unsolicited e-mail from Web sites within it and allows them to browse anonymously on the Web. A time it allows Web sites to conduct analysis of site usage and aggregate user preferences. The I/CODE system has proven to be popular among users registered in the first ten weeks of its operation, and about 25,000 new subscribers are joining per week. (8)

The Internet Profiles representative opined that a universal registration system is preferable to a system of online disclaimers and notices, because the latter interferes with the interactivity of the online medium. (9)

2. Cookies

Before the advent of "cookies" technology, a Web site's server was unable to know whether the downloading of separate pages within the same Web site was for a single user or many different users. (10) Cookies were invented to enable the Web site's server to keep track of a particular user's activity within the Web site. Cookies technology allows the Web site's server to place information about a user's visits to the site on the user's machine in a text file. (11)

Using cookies, a Web site assigns each user a unique identifier (not the actual identity of the user), so that the user may be recognized in subsequent visits to that site. (12) On each return visit, the site can call up user-specific information, which could include the user's preferences, interests, as indicated by documents the user accessed in prior visits or items the user clicked on while in the site. (13) An expiration date allows cookies to be set to remain on a user's machine either permanently or for a specified length of time. (14) Cookies also vary in the security they provide for the information they contain. (15)

Cookies can store information that facilitates the interaction between user and Web site. As an example of how a permanent cookie functioned, consider the online version of a newspaper. If a subscriber whose native language is Spanish informs the Web site that he prefers to do Spanish edition of the newspaper, the newspaper can store that information in a cookie file on the user's hard drive. When the subscriber enters the newspaper's Web site, the site retrieves the language preference information from the cookie and automatically sends the Spanish language edition to the user. (16) Temporary cookies can be created during online shopping expeditions. The cookies can tag the shoppe intended purchases to facilitate the ordering process and then expire after a purchase is made. (17)

According to the representative of Netscape Communications Corporation, cookies technology could be used by Web sites to facilitate communication of consumers' privacy preferences. (18) Once a user communicated his or her privacy preferences in response to a Web request from the site, the user may opt to disclose his or her e-mail address, in order to receive future communications from the site, and forwards the user's name and street address to the site. Personally identifying information is not sent to the site without the user's consent. (6) All of the personal information transmitted between I/CODE and sites registered in the I/CODE system is encrypted. I/PRO aggregates sites within the I/CODE system are contractually bound not to share or sell collected personal information to entities outside the I/CODE system.

The Internet Profiles representative opined that a universal registration system is preferable to a system of online disclaimers and notices, because the latter interferes with the interactivity of the online medium. (9)
notice of its information practices, the site could store that information in a cookie text file on the user's hard drive. The dialogue around preference, notice, and consent that initially took place between user and site would, therefore, not have to be repeated in subsequent visits. (19)

3. Platform for Internet Content Selection (PICS)

The World Wide Web Consortium at the Massachusetts Institute of Technology developed its Platform for Internet Content Selection (PICS) to enable parents to block their children's access to Internet sites whose content the parents deem objectionable. (20) PICS establishes a set of "labeling" Internet sites on the basis of their content and for creating label-reading software to block access to some sites and permit access to others based upon the labels. PICS is a set of technical specifications, a standard format for labels; it is neither software nor label, but a language that allows software and label to work together. (21)

PICS itself is "viewpoint-neutral." (22) Anyone can develop a set of content-rating criteria (identifying "hate speech," for example, or "excess nudity"), create a labeling vocabulary, evaluate Internet sites, and use the PICS specifications to label sites accordingly. Labels are affixed to electronic documents such as home pages on the World Wide Web by site owners or third parties — parent groups, religious groups, or concerned groups — who can locate their labels on agreed-upon sites. Software capable of reading labels in the PICS format may be developed independently of these labels. This software automatically checks for the labels and blocks access to sites based upon the labels. (23) Thus, if a user's browser has been configured to block electronic documents labeled as "excessively violent" by a site-rating service that screens Web sites for such content, the user will deny access to any site to which the rating service's "excessive violence" label is affixed. The user can override the software's action through use of a password. (24)

The use of PICS technology for content-blocking purposes is proliferating. (25) Several panelists noted that PICS technology could be used to enhance online privacy. (26) Industry groups, privacy advocates, and consumer groups could use existing PICS technology to create rating services based upon the privacy-protectiveness of Web sites' information practices, and these systems could then be used to block access to sites whose practices would not meet the users' preferences. (27) If, for example, a consumer group created an index of privacy-protective Web sites based upon a review of the site's information practices, a user could set her PICS-compatible browser to allow access only to sites labeled as being in the index. The label-reading software would block access to sites that were not on the list. (28)

PICS technology might be extended further to allow more sophisticated notice and choice options. The prerequisite to extending PICS technology would be a standard format for describing information practices and user preferences as to how their information should be used. (29) A user's preferences (e.g., "no restrictions on use" or "no transfers to third parties") on his computer with software that employs this format would similarly give notice of their information practices (e.g., "we do not sell or rent our customer list to other companies"). The user's browser would be capable of automatically comparing his preferences with sites' practices, as the user moves around the World Wide Web. Particular Web sites' practices matched the user's preferences, notice and choice would occur "seamlessly" in the background, and the user would proceed to enter the site. If there were a mismatch, the user's software would alert him to that fact. (31) The Web site could respond by providing an explanation for the mismatch, or offering the user an opportunity to view its information policy. (32) The Web site could offer the user an in-context such as discounts in exchange for the user's agreement to accept the site's information practices. (33) Finally, extended PICS technology theoretically enable this sort of negotiation about notice and choice to be automated. (34)

4. Participants' Views on the Demonstrated Technological Approaches

Workshop panelists agreed generally that the technologies demonstrated are promising means of advancing consumer privacy. (35) The disagreement, however, as to whether these technologies are sufficient to address the full range of online privacy concerns. For some participants, the technologies including encryption, that allow individuals to use the Internet anonymously, offer more effective privacy protection. (36)

Participants devoted considerable time to the PICS technology, and raised several concerns. Representatives of the direct marketing and information industries viewed filtering technologies such as PICS as "blocking technologies" that give consumers a "no" vote on entire categories of information content available online. IIA opined that use of PICS to block information by category, rather than on a case-by-case basis, would unacceptably restrict commercial speech. (37) A DMA representative shared this concern and asserted that filtering technologies such as PICS should be paired with technology that allows consumers to release information alerting marketers to the kinds of products and services they would be willing to accept solicitations. In DMA's view, this would balance consumers' privacy with the needs of businesses whose investments are crucial to the success of the online marketplace. (38)

Others expressed concern that a PICS-based model for notice and consent would be too complicated and frustrating for consumers, especially if they were continually required to reset their privacy preferences. (39) One panelist argued that this model would unjustifiably shift the burden of burdening consumers to take affirmative steps to protect their privacy. (40) A representative of the advertising industry opined that online interactions could disrupt the substantive dialogue between marketer and customer (or potential customer). According to this panelist, such interactions would be critical. (41)

PICS proponents countered that any use of the Internet requires many affirmative steps and that the additional steps consumers would have to take to express privacy-related choices would not be burdensome. (42) PICS, they argued, empowers individuals to express a broad range of preferences and enables Web sites to respond to the variations. (43) Technology like PICS, which builds an information profile, works in the background and need not interrupt the communication between the user and a Web site. (44) According to one panelist, it would be possible to create a system in which users would set their privacy preferences once, and the question of compatibility of their privacy preferences and Web sites' privacy policies would be resolved automatically through communication between computers. (45)

Privacy advocates expressed the concern that PICS technology is valuable only where a consumer is interacting directly online with an entity seeking to use his or her personal information. (46) For this type of interaction, these participants agreed that PICS provides useful tools...
enhancing notice and choice.(47) These panelists argued, however, that PICS does not address the online use of a consumer's personal information by entities with whom that consumer has had no direct relationship.(48) Yet the unauthorized collection and use of personal information is continually evolving, and several panelists suggested that it can be shaped to create electronic privacy protections in relatively short order. Industry representatives and trade associations took the position that it would be both inappropriate and counterproductive to mandate particular privacy protections. According to these participants, regulation would stifle the creativity and innovation that have made the development of interactive media possible.(73) Could infringe important First Amendment rights.(74) And might force marketers off the Internet entirely.(75) Government should step back, it was argued, and permit industry to develop privacy protection models.(76)

The extension of PICS technology to interactions between users and Web sites around notice and choice issues is currently a theoretical possibility. An extended PICS regime will require a standard vocabulary for describing Web sites' information practices and for labeling Web sites.(49) Web site self-labeling, coupled with third party certification of label accuracy, was said to be a more efficient approach. The extension of PICS to interactions between users and Web sites around notice and choice issues is currently a theoretical possibility. An extended PICS regime will require a standard vocabulary for describing Web sites' information practices and for labeling Web sites.(50) Web site self-labeling, coupled with third party certification of label accuracy, was said to be a more efficient approach. (51)

Ultimately, there was considerable optimism that an online notice and choice regime based upon PICS technology is attainable. The online notice and choice regime is continually evolving, and several panelists suggested that it can be shaped to create electronic privacy protections in relatively short order. Industry representatives and trade associations took the position that it would be both inappropriate and counterproductive to mandate particular privacy protections. According to these participants, regulation would stifle the creativity and innovation that have made the development of interactive media possible.(52) Could infringe important First Amendment rights.(53) And might force marketers off the Internet entirely.(54) Government should step back, it was argued, and permit industry to develop privacy protection models.(55)

B. Consumer and Business Education

Workshop panelists agreed that consumer and business education is an indispensable component of any strategy to protect consumer privacy online and ensure the growth of the online marketplace. As several panelists pointed out, consumers generally know little about the way personal information can be used online.(56) They do not understand the potential risks of divulging personal information online, and the guidance on how to protect that information from unauthorized use.(57) This is true for both new and seasoned users of the Internet.(58) Consumers also need to understand the trade-offs in order to make an informed decision to divulge personal information online.(59) Panelists noted that business must be educated about the importance of privacy protection to the growth of the online marketplace.(60) and that businesses, in particular, must be shown the benefits to their enterprise of protecting the privacy of personal information.(61)

Several panelists stated that industry, consumer groups, and government all have a role to play in educating consumers and businesses about online privacy issues.(62) Such efforts should proceed on many fronts and in many media. Panelists urged that educational efforts be comprehensive, taking advantage of the interactive nature of the online marketplace and include fresh approaches. Computer companies, for example, could include point-of-sale materials with each new computer.(63) Panelists also urged that consumers be involved in education efforts and that such efforts be directed toward the elderly, who are increasingly active on the Internet,(64) and toward young people.(65)

Several panelists noted that the power of new electronic technologies can be harnessed for further education efforts. Individual online education and research programs provide guidance for protecting information privacy online, and interacts with consumers across the country and around the world through its site on the Internet.(66) In March 1995, ISA and the National Consumers League (NCL) launched Project OPEN (the Online Privacy Education Network) to educate consumers on important online issues, including privacy.(67) There was a suggestion that the Commission should intervene promptly to protect online privacy. In their view, purely self-regulatory approaches to protecting privacy online will fail.(68) And might force marketers off the Internet entirely.(69) Government should step back, it was argued, and permit industry to develop privacy protection models.(70)

C. Participants' Views on Self-Regulation and Government's Role

Throughout the first day of the Workshop, participants expressed differing views of the role government should play in the area of online privacy protection. Industry representatives and trade associations took the position that it would be both inappropriate and counterproductive to mandate particular privacy protections. According to these participants, regulation would stifle the creativity and innovation that have made the development of interactive media possible.(71) Could infringe important First Amendment rights.(72) And might force marketers off the Internet entirely.(73) Government should step back, it was argued, and permit industry to develop privacy protection models.(74)

According to these panelists, market pressures will define the best privacy protections.(75) As consumers increasingly make known their preferences regarding information privacy online.(76) In their view, it is critical that government permit the development of a healthy marketplace for online privacy protections.(77) Moreover, according to several panelists, regulation is an insufficiently precise method of shaping informa online. Given the rapid pace of technological development in interactive media, government regulations tied to particular technologies will quickly become obsolete.(78)

Panelists strongly disagreed about whether emerging technologies would obviate the need for governmental regulation to protect online privacy. ISA's representative saw PICS as an especially important alternative to government regulation in the global online marketplace. Regulation by the geographic boundaries of the regulating jurisdiction; but PICS can operate globally to benefit both industry and consumers. Privacy advocates argued that the technologies demonstrated during the Workshop are not a substitute for an enforceable code of fair information practices, and that they are not likely to flourish without government enforcement of privacy rights.(79) One panelist urged the Commission to mandate particular privacy protections. According to these participants, regulation is an insufficiently precise method of shaping information online. Given the rapid pace of technological development in interactive media, government regulations tied to particular technologies will quickly become obsolete.(80)

According to these panelists, market pressures will define the best privacy protections.(81) And might force marketers off the Internet entirely.(82) Government should step back, it was argued, and permit industry to develop privacy protection models.(83)

Panelists offered various opinions on the role the Commission should play in protecting individual privacy online. Some privacy advocates that the Commission should intervene promptly to protect online privacy. In their view, purely self-regulatory approaches to protecting privacy online will fail.(84) Self-regulation will not be effective, according to these participants, unless regulation operates in the background to deter bad behavior. Otherwise, companies that abide by self-regulatory guidelines will be at a competitive disadvantage.(85)
Some participants suggested that the Commission should undertake research on issues related to information privacy online. Several urged, for example, that the Commission conduct focus groups with users of online services and with consumers generally, to obtain an understanding of their expectations and experiences regarding online privacy and to assess issues such as consumers' willingness (or lack thereof) to divulge personal information in return for customized products and services. (86)

Finally, several panelists stated that the Commission has the authority to step in where online information collection and use are shown to be fraudulent or deceptive, in violation of the Federal Trade Commission Act. (87) Law enforcement was said to be appropriate where, for example, a company misrepresents the nature of its online information practices or fails to adhere to the practices it has announced. (88)

28. Id. at 21.
29. CDT Comment at 4 (not paginated) (Doc. No. 22); Resnick 87. At this time there is no agreed-upon vocabulary for describing particular information practices as "privacy protective." However, a hypothetical application of PICS technology, using the Canadian Standards Association (CSA) 1996 Model Code for the Protection of Personal Information as the basis for such a rating vocabulary, was demonstrated at the W3C's Workshop on Privacy Protection. In this hypothetical scenario, the user’s browser is configured to locate Web sites that carry a CSA label. PICS technology gives the user flexibility to set his preferences to reflect the degree to which he is concerned about various requirements of the CSA Code. If, for example, he is willing to access sites that comply with some but not all Code provisions, he can so indicate. If he does not want to do business with site operators that are in full compliance with the Code, he can set his preferences accordingly and the software will block access to non-complying sites. Resnick 83-85.

30. According to CDT, the ability to pre-set the user’s preferences is more protective of privacy than a model that forces the user to decide to opt-out of a site’s information practices on a transaction-by-transaction basis. Comment at 4 (not paginated) (Doc. No. 22).
