Overview

Software developers have responded to concerns about protecting children from objectionable content on the Internet by developing "filter software" to enable parents and other supervising adults to set content and access preferences for children. Most filters currently act as content filters. Software companies are now working to add privacy preferences to their content filters. In the future, label-reading software enable consumers to set their computers to access only those Internet sites whose privacy policies match their privacy preferences.

Content screening software uses either a filtering or rating method. The filtering method allows access to the Internet, but blocks the site materials) that the software publisher defines as objectionable. Typically, the software recognizes a database of banned sites and search The database, however, requires regular updating, which may be at a cost to users through subscriptions. This design is not foolproof. It prevent a user from clicking on a link to a site that is not in the database, and it cannot stop a clever search that avoids the search words the database.

The rating method blocks access to sites that do not bear a particular rating. The two currently operational rating systems are Recreational Software Advisory Council on the Internet (RSACi)(1) and SafeSurf(2). Rating programs identify a site's HTML code and only those that code with the rating are allowed through. Parents can, for example, restrict their children's access to sites that are rated as having no sexual material, foul language, or violence. This rating method uses the Platform for Internet Content Selection (PICS) specifications described II of this Workshop report. SafeSurf and RSACi use the PICS format, but rely on Web sites to rate their own pages, while they reserve the right to verify each site's rating. Only a minority of existing Web sites is currently rated by these systems. Filtering software companies can add blocked sites to their databases on an ongoing basis. Rating systems, however, are largely relying on Web sites to insert rating labels or sites, and sites have been slow to do so.

The explosive growth of the Internet makes it very difficult for software programs to completely monitor and control access to Internet sites, even if a list of blocked sites is installed, thousands of new sites may have appeared. Moreover, since only a small percentage of existing sites have been reviewed, unreviewed Web sites are screened using search or trigger words or phrases. Objectionable sites, however, can still slip past the filters. For example, a new site may have a Web address that appears to be innocuous, but may in fact contain objectionable content. Manually screened, it may not be filtered out. In addition, a site may contain explicit graphics alongside unrelated text, which cannot be caught even by software that filters full text as it appears on the screen. Foreign languages and unusual spellings may also bypass filter software.

Conversely, unintentional blocking may occur, preventing access to harmless medical and historical data. Phrases with dual meanings can also cause unintentional blocking. For example, a site containing Hitler's name or the word "fascism" may be blocked because the filter screens for hate content. To some extent, if the software can be customized, some of these problems can be alleviated by allowing the adult to adjust the software's lists.

The various filtering software products offer a wide range of features. The least complicated software simply maintains a list of Web site and blocks user access to the sites on the list. Some products offer the option of using lists and employing PICS compliant rating systems. The rating method requires a more complex setup filter. Many programs offer a monitoring option, which creates a record of where the user attempted to go and when. This can be an addition to or as an alternative to blocking access. Programs may also shut down an application entirely or e-mail the "Administrator" attempt to access a blocked site. Filtering can vary as well, from one-way, where only the incoming text is screened, or two-way, where both user types (i.e., a computerized order form or e-mail) are also monitored. Two-way screening is useful to prevent the flow of personally identifiable information. Two-way screening occurs in conjunction with custom lists of blocked terms, including names, addresses, birth dates, and other information. Currently only four products, CyberPatrol, Cybersitter, Net Nanny, and Spec's for Kids, are able to prevent a child from sending blocked information. While some products are limited to interactions on the Internet, many give users the option to continue screening of word processors, games, financial managers, and any other software on the computer.

Server-based filtering options, available more commonly for business use, install filters directly on the server of a system of computers (i.e., Local Access Network). This option serves all computers directly attached to the network, as well as those connecting through a dial-up modem. Most filtering packages created for home use, however, are client-based, meaning software is installed directly by the user and to their system, regardless of their mode of online connection (modem, LAN, etc.). While the difficulty of setup varies, all software packages are fairly simple. The actual installation, whether the software is downloaded from the Internet to the hard drive or by floppy disk, occurs in a matter of minutes. Configuration is more complicated, and the time needed is directly related to the complexity of the software. Those which offer customizable lists, multi-user options, PICS compliant lists, and other choices take longer to set up and master. Most instructions are clear and technical support is readily available with each package, making it possible to get any software package up and running in a short period. Though prices vary, many home and school editions are available for free or at a low cost. Many server-based online services provide filter software at no additional cost to their members.

Major Online Services
Each of the major online providers is increasing its efforts to create a safer environment for children using the Internet. America Online (parents a number of blocking options. Parents may limit their children's access to the "Kids Only" or the "Teens Only" areas, which consist of preselected entertainment and educational sites, as well as adult monitored chat and message areas. Users are kicked out of a chat room if they deem their language to be inappropriate. AOL's Member Profile, e-mail, and chat areas permit extensive collection of personal information. A parent may block a child from all chat rooms and Internet newsgroups on AOL. The option of presetting billing limits is also available.

Prodigy provides parents with the option to control access to its individual bulletin boards, chat areas, or newsgroups. Parents can also complete access to the Web for certain users. Prodigy offers kids and teen chat rooms, as well as special Web areas exclusively for children. Prodigy also makes Cyber Patrol available to its members. Within Prodigy's chat rooms and public forums, users are prevented from entering if their language is deemed unacceptable for children.

CompuServe offers parents the option of controlling which areas members of the family can enter by using passwords. No chat areas are available for children. Parents have the option of having e-mail sent to them first for screening before a child receives it. CompuServe also makes Cyber Patrol available to its members.

Microsoft's new browser, Internet Explorer 3.0, offers a built-in parental control feature. Through the "Ratings" options menu, the Administrator can select to block access to a site or single page based on a number of content categories, e.g., violence, nudity, and adult language. The parental controls are based on the RSACi standard, but the Explorer will also support ratings from any organization that follows the PIC standard.

SUMMARY OF FILTERING SOFTWARE

SurfWatch

SurfWatch, by Spyglass Inc., screens for objectionable content (violence, hate crimes, drugs/alcohol and sex) on the Web and in chat rooms. SurfWatch screens using a list of objectionable Web addresses (updated monthly) and specific trigger words within an address. Unreviewed and those that do not contain the identified trigger words within their Web addresses may not be blocked. SurfWatch claims to block over 100,000 sites. SurfWatch does not work with the online services. The Administrator can independently update the SurfWatch lists or create his or her own blocking lists.

Cybersitter

Developed by Solid Oak Software, Cybersitter filters the Web, newsgroups, chat rooms, and e-mail and also offers the option of blocking applications, including games. It blocks sites related to adult themes such as sex, hate, violence, and drugs. Most importantly, Cybersitter addresses privacy issues by offering a custom blocking service, allowing a user to create a list of words and phrases that screen both incoming and outgoing information, in addition to the default restrictions. This can prevent the transfer of information such as credit card numbers or personally identifiable information. Its "Advanced Phrase Definitions Capabilities" allows a user to offer sentence combination possibilities live at [on] [1234] [Main Street] to maximize the prevention of the transfer of such information. For additional blocking, a user can choose the PICS standard rating systems, which are included in the package. The program does not block sites that have not been rated by one or more organizations. A unique feature of Cybersitter is its "Intelligent Phrase Filtering" system, which looks at words in context to prevent accidental accidental blocking of phrases with multiple meanings. It also offers the option of logging the sites visited without actually blocking the site.

Net Nanny

Trove Investment Corporation's Net Nanny emphasizes the parents' role in determining what is appropriate for their children, rather than software company's determination. It offers a custom dictionary that is entirely defined by the Administrator. The Administrator can control access to chat areas and Web sites, as well as to an executable on both Windows and DOS, including all online services. To provide assistance, Net Nanny has created a sample dictionary file. Once the list is completed, the package screens both incoming and outgoing information. It also maintains a log of blocked sites and can display the frequency of each type of violation. On request, the Administrator can choose to have the system shut down after a pre-set number of violations has occurred.

Cyber Patrol

Cyber Patrol, a Microsystems Software Inc. product, filters objectionable material on online services, the Web, and chat rooms and contains filtering software programs as long as the Internet connection is maintained. It works with either an exclusive "CyberNot" list or an inclusive or exclusive lists. The Administrator can customize either list to include or exclude particular sites. The Administrator can review a series of content categories and choose those that are appropriate for each user. Cyber Patrol is not able to filter new sites with nonidentifiable addresses. It can filter by time of day or by total hours allowed. Upon request, the package can generate reports and chart usage. Cyber Patrol also addresses privacy concerns with its newly added "ChatGard." This feature enables the Administrator to block sites that may contain personally identifiable information using a custom list of words and phrases. When information from this list is typed in, "x" marks appear instead. Cyber Patrol is now offered by AOL, CompuServe, and Microsoft's Internet Explorer. It is also PICS compatible and can read SafeSurf or RSACi ratings.

Net Shepherd

Net Shepherd, marketed by Net Shepherd Inc., enables the Administrator either to independently rate Web pages using an onscreen, per-click ratings bar or to screen sites using any of the PICS compliant rating systems, such as SafeSurf or RSACi. The Administrator can...
sites as "general," "child," "pre-teen," "teen," "adult" or prohibited. Net Shepherd can be configured to block unrated material or to create selected sites. It is not designed to screen sites that do not bear ratings, and it only block sites on the Web and not newsgroups or chat rooms. Net Shepherd Inc. plans to extend the same rating and filtering capabilities to newsgroups.

**Parental Guidance**

Providence Systems markets Parental Guidance, which categorizes sites as "child," "adolescent," or "parent." Parental Guidance has a database over 100,000 sites and offers the option of downloading approximately 20,000 new sites each month. The list of approved Web sites is published by the McKinley Group, which publishes the McKinley Internet Directory. The program also enables the Administrator to restrict access to specific newsgroups and chat areas. While Parental Guidance does not directly target the collection of personal information, the Administrator must add such screening categories as credit cards and advertising, preventing the transfer of some personally identifiable information. One limitation of the program is that it does not prevent a child from transferring information on a site approved by Parental Guidance to an unapproved site.

**Specs for Kids**

Newview, Inc.'s Specs for Kids creates an inclusive environment in which children can explore the Internet. The Specs for Kids home page includes a search tool and links to reference tools, news sources, entertainment, and other pages approved for children's access. In addition, Administrator can customize the software to create a dictionary of restricted words and phrases to override the default inclusive list. An administrator may choose between five different levels of restriction within 15 rating categories, including a whole range of adult topics. Specs for Kids is compliant and has added such screening categories as credit cards and advertising, preventing the transfer of some personally identifiable information. One limitation of the program is that it does not prevent a child from transferring information on a site approved by Specs for Kids to an unapproved site.

**InterGo Communications**

TeacherSoft's InterGo Communications is a filter and an Internet access package designed to appeal to adults and children. After installation view a "desktop" home page: a literal image of a desk from which point and click functions lead the user to various online functions. In addition, e-mail, educational resources, and Internet search functions. Administrators can set up multiple users with individual settings, depending on preferences. InterGo's "KinderGuard" system filters sites based on five levels ranging from EC (early childhood) to AO (adults only). In addition, SafeSurf ratings can be selected. InterGo screens out objectionable material from the Web, chat rooms, newsgroups, and mail. The Administrator can customize the KinderGuard list by adding specific Web addresses to block; however, it cannot screen for words or phrases thus limiting its ability to block the transfer of personal information. It also supports SafeSurf. Its "Cybrarian Search" feature is an Internet tool that checks sites (including Web documents, reference materials, news and discussion groups) for offensive words and assigns a rating.

**Bess**

Bess is a server-based filter, which is available for online subscription. Subscribers dial into Bess and use the Bess browser. Bess offers preselected sites and blocks entire Web sites or individual pages, depending on the amount of inappropriate material. Access to selected newsgroups is an option, but chat areas are not accessible. Both incoming and outgoing e-mail are screened for inappropriate language offers the benefits of a continually updated service provided through the server and is resistant to tampering, since the controls are located at the server.

---

1. The Recreational Software Advisory Council (RSAC), an organization initially formed by software publishing companies in 1994 to rate game software for violence, adapted its rating system to the Web and expanded the categories to include ratings for the level of violence, nudity, and offensive language. The RSAC asks Web sites to create ratings for their own pages by answering a questionnaire at the RSAC site. After completing the questionnaire a PICS-compatible HTML tag is designated and the site can insert it into its pages. The tag is then added to the RSAC ratings system. The RSAC reserves the right to verify the accuracy of each rating. A number of the filters described in this appendix support the RSAC ratings system, including Cyber Patrol, Microsoft Internet Explorer 3.0, Net Shepherd, and SurfWatch.

2. SafeSurf was begun by a group of parents in 1995 to create a "child safe" environment on the Internet. Its Web site provides HTML tags that Web sites can use to rate their sites according to SafeSurf's criteria.

3. This appendix uses the term "Administrator" to refer to the person who controls the implementation of the filtering software, i.e., the teacher or employer who installs and configures the software program.
