The Effect of Privacy Regulation on the Data Industry: Empirical Evidence from GDPR

Guy Aridor†  Yeon-Koo Che‡  Tobias Salz§

June 9, 2020

Abstract

Utilizing a novel dataset from an online travel intermediary, we study the effects of EU’s General Data Protection Regulation (GDPR). The opt-in requirement of GDPR resulted in 12.5% drop in the intermediary-observed consumers, but the remaining consumers are trackable for a longer period of time. These findings are consistent with privacy-conscious consumers substituting away from less efficient privacy protection (e.g., cookie deletion) to explicit opt out—a process that would make opt-in consumers more predictable. Consistent with this hypothesis, the average value of the remaining consumers to advertisers has increased, offsetting some of the losses from consumer opt-outs.

Keywords: GDPR, Data Privacy Regulation, E-Commerce

JEL Codes: L00; L50; K20; L81.

1 Introduction

Technological advances in the past several decades have led to enormous growth in the scale and
precision of consumer data that firms collect. These advances have been followed by progress in
machine learning and other data processing technologies that have allowed firms to turn data into
successful products and services and earn vast economic returns along the way.\(^1\) However,
at the same time, there has been an increasing number of high profile data breaches and a grow-
ing feeling of despondency amongst consumers who lack control over this process.\(^2\)\(^3\) Beyond
the immediate economic harm resulting from such data breaches consumers might also value
privacy for its own sake and feel uncomfortable if excessive data gathering makes their behavior
too predictable.\(^4\) Against this backdrop, government regulators have proposed and enacted data
privacy regulation that empowers consumers to have more control over the data that they gen-
erate. The European Union was the first to enact such legislation, the General Data Protection
Regulation, which has served as a blueprint for privacy legislation in California, Vermont, Brazil,
India, Chile, and New Zealand.\(^5\) However, we lack empirical evidence on the effectiveness and
broader impact of such regulation. Such evidence is critical not only for guiding the design of
upcoming regulation, but also to understand fundamental questions in the economics of privacy.

This paper empirically studies the effects of the EU’s General Data Protection Regulation (GDPR), in
particular, its requirement that consumers be allowed to make an informed, specific, and
unambiguous consent to the processing of their data. The consent requirement provides a
frontline defense of privacy for consumers: by denying consent, a consumer can block a website
from collecting personal data and sharing it with third-party affiliates. At the same time, consent
denial inhibits firms from tracking consumers across time and across websites, thereby building
historical profiles of consumers. Without them, these firms may not be able to learn and predict
consumer behavior and target their services and advertising accordingly.

\(^1\)Several popular press outlets have gone as far as stating that “data is the new oil” meaning that the
world’s most valuable resource is now data, not oil (e.g. The world’s most valuable resource is no

\(^2\)There have been many but among the most prominent are the Cambridge Analytica and Equifax data breaches. Cambridge Analytica harvested the personal data of millions of people’s Facebook profiles without their consent and used it for political advertising purposes. The Equifax data breach exposed the names, dates of birth, and social security numbers of 147 million individuals.

\(^4\)For the different motivations for privacy, see, for instance: Acquisti, Taylor and Wagman (2016)

\(^5\)While such regulation is not entirely novel, the scope and robustness of previous regulation pales in comparison to that of GDPR. Several states in the United States and countries around the world are debating and implementing their own privacy regulations with similar scope and stipulations as GDPR. For more information on the specifics of the various laws and how they relate to GDPR: 6 New Privacy Laws Around The Globe You Should Pay Attention To. https://piwik.pro/blog/privacy-laws-around-globe/. Retrieved on March 10th, 2020.
Our investigation focuses on three broad questions. First, to what extent do consumers exercise the consent right enabled by GDPR? Anecdotal and survey evidence suggests that consumers value their privacy. Yet, as commentators argue, consumers may not be willing to act on their privacy concerns even at little cost or inconvenience. We do not yet have clear empirical answers on this question, and consumers’ decisions in their GDPR opt-out could shed light on their “revealed” value of privacy.

Second, how does GDPR change the composition of consumers observed by firms? Even prior to GDPR, consumers were able to protect their privacy by utilizing browser-based privacy protection means. However, utilizing these privacy means does not eliminate their footprints altogether but rather simply generate “spurious” identifiers that are difficult for firms to distinguish from genuine footprints left by consumers who do not adopt them. This process creates noise in the data observed by firms that could make it difficult for them to track consumers and predict their behavior. Under the GDPR regime, however, the same consumers may simply opt out, in which case they do not leave any footprints, and this could in principle make the remaining consumers more easily trackable and identifiable. This raises an interesting question of externalities created by privacy tools on the other consumers and for the firms. To the best of our knowledge, these forms of privacy externalities not only differ from those recognized in the theoretical literature (Choi, Jeon and Kim, 2019; Acemoglu et al., 2019; Bergemann, Bonatti and Gan, 2019) but more importantly have never been empirically identified.

Third, how does the GDPR privacy protection impact firms that rely crucially on consumer data? Specifically, how does consumer opt-out affect firms’ abilities to learn and predict consumer behavior and to provide targeted advertising? And how do advertisers react to such a change? These questions are particularly important for the competitive landscape of the digital economy. While big technology firms such as Google or Facebook enjoy virtually unlimited access to consumer data based on their extraordinary reach and presence, many third-party companies can only access the data shared by first-party affiliates. A concern is that the playing field of these firms, already threatened by the big tech companies, may be further weakened by the increased consent requirement of data regulation. How such a third-party firm copes with GDPR could

---

6A prevalent theme in the economics of privacy literature consistently finds a privacy paradox - the apparent inconsistency between individual’s strong stated preferences for privacy and their willingness to give away personal information at little cost (Acquisti, Taylor and Wagman, 2016). This directly implies that a natural hypothesis is that consumers may ask legislators for such privacy means but, ultimately, make little use of them.

7This concern has been raised in the recent literature (Johnson and Shriver, 2019; Batikas et al., 2020) and the popular press (GDPR Has Been a Boon for Google and Facebook. https://www.wsj.com/articles/gdpr-has-been-a-boon-for-google-and-facebook-11560789219. Accessed on June 2nd, 2020) which show that GDPR led to an increase in market concentration of web trackers, favoring those from Google and Facebook. This concern is further exacerbated by the sheer scope of these companies that allows them to collect data across many different devices and domains that are not feasible for smaller third-party vendors (All the Ways Google Tracks You—And How to Stop It. https://www.wired.com/story/google-tracks-you-privacy/. Accessed on June 2nd, 2020).
provide a valuable clue on how data regulation may influence the competitive playing field of the
digital economy.

To answer these questions, we use the data provided by an anonymous intermediary that
operates in more than 40 countries and contracts with many of the largest online travel agencies
and travel meta-search engines. The dataset is uniquely suited for the current inquiries in several
respects. An integral part of the intermediary’s business is to predict the likelihood of purchase
of each consumer upon every visit, based on the identifiable history of past behavior, which it
uses to personalize the experience of consumers on the website.

The data links consumers’ behavior across time and across websites using cookies (set by the
intermediary)—small files stored attached to a consumer’s web browser that allow the intermedia-
yary to identify consumers. We observe (in anonymized and aggregated form) the same rich con-
sumer information as the intermediary and link them just as the intermediary can. If a consumer
does not consent to data storage using GDPR opt-out, then his/her cookies cannot be stored, so
the consumer is no longer observed by the intermediary. We can directly infer consumer pri-
vacy choices from the number of consumer visits as seen by this (third-party) intermediary and
the change in composition, necessary to answer the first two questions. We also observe rev-
enues from keyword-based online advertising, and observe the output of a proprietary machine
learning algorithm that predicts the purchase likelihood, which will help us to address the third
question.

Our empirical design exploits the fact that the intermediary contracts with many different
platforms all around the world who were differentially impacted by the introduction of GDPR.
Furthermore, the machine learning algorithm is trained and deployed separately for each online
travel website. This means that changes in data on one website, due to GDPR or other factors, do
not impact the performance of the algorithm on other websites. We exploit these features of our
data and the geographic reach of GDPR to utilize a difference-in-differences design for several
outcome variables across major European countries and other countries where GDPR was not
implemented.

We find that GDPR resulted in approximately a 12.5% reduction in total cookies, which pro-
vides evidence that consumers are making use of the increased opt-out capabilities mandated by
GDPR. However, we find that the remaining set of consumers who do not opt out are more per-
sistently trackable. We define trackability as the fraction of consumers whose identifier a website
repeatedly observes in its data over some time period. We find that trackability has increased by
8% under GDPR.

We explore the mechanisms behind the increased trackability and argue that the most plausi-
ble explanation is that the individuals who make use of GDPR opt-out are primarily substituting
away from other browser-based privacy means, such as cookie blockers, cookie deletion, and
private browsing. While the latter generates many “bogus” short-lived consumers (as a new ID is assigned to a consumer, thus making her appear as a new user, each time she visits the site), the former—the GDPR opt-out—simply removes these individuals from the data. As a result, those consumers that remain in the data after the implementation of GDPR are more persistently identifiable.

Given this change in consumer composition, we explore the extent to which this affects advertising revenues. In our setting the revenues that we observe come from keyword-based advertising and, further, when consumers opt out they are no longer exposed to advertisements. We find that there is an immediate drop in the total number of advertisements clicked and a corresponding immediate decline in revenue. Over time, though, advertisers on average increase their bids for the remaining consumers, leading to a smaller overall decline in revenue. This indicates that the remaining set of consumers are higher value consumers compared to the pre-GDPR set of consumers. One possible mechanism for this is that the increased identifiability of consumers allows for advertisers to better attribute purchases to advertisements than before. This increased attribution ability leads to an increase in perceived overall value of consumers by advertisers.

Finally, we study the effect that GDPR had on the intermediary’s ability to predict consumer behavior. In particular, we study the performance of the classifier used by the intermediary, which is a crucial element of its business. The classifier provides a prediction of the probability that a consumer will purchase on the website where she is currently searching. We find that there is evidence that the classifier did not immediately adjust to the post-GDPR distribution. However, despite this, we still find that the ability of the classifier to separate between purchasers and non-purchasers did not significantly worsen after GDPR and that, if anything, the changes to the data observed by the intermediary should lead to improvement in its ability to separate between purchasers and non-purchasers.

Our results suggest a novel form of externalities that privacy-conscious consumers exert on the rest of economy—including other consumers and the firms and advertisers relying on consumer data. Their switching away from inefficient browser-based means of privacy protection to an explicit opt-out (enabled by data regulation) could expose the digital footprints of those who choose not to protect their privacy and make them more predictable. These externalities have potentially important implications. First, third-party firms will suffer from loss of consumers who opt out, but this loss will be mitigated by the increased trackability of those consumers who remain. Indeed, our analysis suggests that the mitigating effect could be significant enough for the firms not to be worse off from the increased consent requirement. Meanwhile, the welfare effect on the remaining consumers depends on how their data is used by the firms. If their data is used to target advertising and services to their needs, as appears to be so far the case, the externality is largely positive and they will be also better off. However, if the data is used to extract their
surplus—a possibility in the future—, they could be harmed by the increased trackability.

Related Work

The protection of consumer privacy and its consequences has been studied by economists, legal scholars, and computer scientists for several decades. We contribute to three strands of literature in the economics of privacy.

**Consequences of Data Privacy Regulation:** To the best of our knowledge Goldberg, Johnson and Shriver (2019) is the first paper to examine the economic impact of GDPR on European websites. They similarly adopt a difference-in-differences approach to study the effect of GDPR on the traffic and purchase volume of European websites and find a similar effect size as we do in terms of the reduction in observed website traffic. However, the scope of our data allows us to tie together the consequences of the opt out decisions of individuals with consumer identifiability, advertising revenues, and effectiveness of prediction technologies. This allows us to go beyond direct measurement of the impact of GDPR and further understand the externalities associated with individual privacy decisions and their indirect economic impact.

Several other papers have studied the impact of the GDPR in other domains (Jia, Jin and Wagman, 2018; Zhuo et al., 2019; Utz et al., 2019; Degeling et al., 2018). Batikas et al. (2020); Johnson and Shriver (2019) show that GDPR increased market concentration amongst web technology services. Goldfarb and Tucker (2011); Johnson, Shriver and Du (2020) study the effectiveness of previous data privacy regulations on online advertising. Finally, Johnson (2013) estimates a structural model of advertising auctions and shows through counterfactual calculations that advertisement revenue drops substantially more under an opt-in rather than an opt-out policy. We complement these papers by utilizing the scope of our setting to tie each of these pieces together and characterize how they interact with each other and are impacted by data privacy regulation.

**Information Externalities:** An important consequence of a consumer’s privacy decision is the informational externality generated by that decision, as information revealed by one consumer can be used to predict the behavior of another consumer.\(^8\,^9\) Several recent theoretical studies ar-

---

\(^8\)There is also an emerging, broadly related, literature that studies implications of a more data-driven economy (Goldfarb and Tucker, 2012a; Einav and Levin, 2014; Chiou and Tucker, 2017; Kehoe, Larsen and Pastorino, 2018; Aridor et al., 2019; Bajari et al., 2019).

\(^9\)Implicit in the study of the effect on consumer predictability is the notion that privacy is not simply about the revelation of a consumer’s information but also the ability of a firm to predict the behavior of a consumer. The idea that privacy is additionally a statistical notion is a common thread in the literature on differential privacy (Dwork, 2011; Dwork, Roth et al., 2014). Differential privacy studies the marginal value of an individual’s data for the accuracy of a statistical query and gives a mathematical framework for trading off the privacy loss of an individual revealing her information and the marginal change in the accuracy of a statistical query. For a discussion of the economic mechanisms at play in differential privacy based methods, see Abowd and Schmutte (2019). While the
gue how such externalities can lead to the underpricing of data, and results in socially excessive data collection (Fairfield and Engel, 2015; Choi, Jeon and Kim, 2019; Acemoglu et al., 2019; Bergemann, Bonatti and Gan, 2019; Liang and Madsen, 2019). Braghieri (2019) theoretically studies how privacy choices by consumers can have pecuniary externalities on other consumers by affecting firms’ incentives for price discrimination. The current paper identifies a novel form of informational externalities. While the existing research focuses on how a consumer’s decision to reveal her private data can predict the behavior of, and thus can inflict externalities on, those who do not reveal their data, we recognize externalities that run in the opposite direction. Namely, we show that the decision by a privacy-concerned consumer to switch from obfuscation to a more effective GDPR-enabled opt-out may increase the trackability of, and thus exert externalities on, the opt-in consumers who choose to reveal their data. More importantly, to the best of our knowledge, this is the first paper that identifies privacy externalities empirically.

Preferences for Privacy: The broader literature on the economics of privacy, recently surveyed in Acquisti, Taylor and Wagman (2016), has studied the privacy preferences of individuals. One prevalent research strand is understanding the privacy paradox, which is the apparent disparity between stated and revealed preference for privacy. In particular, consumers state a strong preference for privacy, but are willing to give up their personal information for small incentives (Berendt, Günther and Spiekermann, 2005; Norberg, Horne and Horne, 2007; Athey, Catalini and Tucker, 2017). Acquisti, John and Loewenstein (2013) use a field experiment to evaluate individual preferences for privacy and find evidence of context-dependence in how individuals value privacy. Using stated preferences via a survey Goldfarb and Tucker (2012b) show that consumer’s privacy concerns have been increasing over time. Lin (2019) shows via a lab experiment that consumer privacy preferences can be broken down into instrumental and non-instrumental components. Our study contributes to this literature by analyzing consumer privacy choices made in a consequential setting, instead of only looking at stated preferences. We find that a significant fraction of consumers utilize the privacy means provided by GDPR, giving suggestive evidence that consumers do value their privacy in consequential settings and not only say that they do.

The paper is structured as follows. Section 2 overviews the relevant details from European privacy law and consumer tracking technology. Section 3 describes the data and empirical strategy that is used for this study. Section 4 provides evidence on the degree to which consumers make use of the privacy tools provided by GDPR. Sections 5 and 6 analyze the extent to which this affects online advertising revenues and prediction, respectively. Section 7 concludes.

intuition behind differential privacy is similar to what we study, we do not explore the design of algorithmic privacy tools. Rather, we empirically document the statistical consequences of privacy choices made by individuals on the predictability of others.
2 Institutional Details

In this section we discuss European privacy laws and the relevant details of the General Data Protection Regulation. We will then describe how websites track consumers online and how GDPR can affect such tracking.

2.1 European Data Privacy Regulation

GDPR was adopted by the European Parliament in April 2016. Companies were expected to comply with the new regulations by May 25th, 2018.\footnote{GDPR was intended to overhaul and replace the Data Protection Directive which was enacted in 1995. GDPR further complements the other major European Privacy Regulation, The Privacy and Electronic Communications Directive, also known as the "Cookie Law". Relative to this law, GDPR strengthened the territorial scope to include data generated by EU consumers, no matter the location of the firm processing the data, and strengthened the degree of firm transparency and stipulations on consumer consent.} It required substantial changes in how firms store and process consumer data. Firms are required to be more explicit about their data retention policy, obligating them to justify the length of time that they retain information on consumers and delete any data that is no longer used for its original purposes. Furthermore, it required firms to increase the transparency around consumer data collection and to provide consumers with additional means to control the storage of personal data.

The primary component of GDPR that we focus on is the new data processing consent requirement. Under the regulation firms need informed, specific, and unambiguous consent from consumers in order to process their personal data, which requires consumers to explicitly opt into data collection. Recital 32 of the regulation spells out what consent means:

\begin{quote}
Consent should be given by a clear affirmative act establishing a freely given, specific, informed and unambiguous indication of the data subject’s agreement to the processing of personal data relating to him or her, such as by a written statement, including by electronic means, or an oral statement. This could include ticking a box when visiting an internet website, choosing technical settings for information society services or another statement or conduct which clearly indicates in this context the data subject’s acceptance of the proposed processing of his or her personal data. Silence, pre-ticked boxes or inactivity should not therefore constitute consent.
\end{quote}

Panel (a) of Figure 1 shows an example of a post-GDPR cookie policy from the BBC, a news organization based in the United Kingdom, and panel (b) of Figure 1 shows a cookie policy of a firm in the United States. The former highlights the specifications of the law, specifying what type of cookies are stored for what purposes and giving consumers the opportunity to opt out from them individually. The latter has no explicit option for the consumers to opt out of data
collection. Instead, it directs consumers to use browser-based privacy means, which allow to control the website’s cookies.

Figure 1: Example Consent Notifications
(a) Post-GDPR consent dialog

(b) Standard opt-out on US websites

Notes: The top panel shows a GDPR opt in consent dialog for the BBC. The dialog is explicit about the data that the website collects and requires the consumer to opt into all non-essential data collection. Each separate purpose of data processing is consented to individually. The bottom panel shows an “opt out” dialog for a website in the US that is not required to be GDPR compliant. The website directs consumers to manage their browser cookies and does not have any direct options for the consumer to opt out of data collection.

The consent requirement is an important component of the law, though there were many other stipulations of the law that enhanced consumer privacy protection and required substantial changes by firms in order to be in compliance. The fines for non-compliance with the legislation are large - the maximum of €20 million, or 4% of total global annual sales for the preceding financial year - giving strong incentives for firms to comply with the regulation. According to PricewaterhouseCoopers, many firms are spending millions of dollars in order to comply with the regulation.11 However, despite this observation, there was still considerable non-compliance around the onset of the law and in the next section we will discuss how this non-compliance

---

affects the interpretation of our estimates.

2.2 Consumer-Tracking Technology

The primary consumer tracking method that we focus on in this study are web cookies. Cookies are small text files that are placed on consumer’s computers or mobile phones. The attachment of a cookie gives websites, in principle, a persistent identifier. As long as the same cookie persists, they can attribute different sessions to the same consumer and, as a result, track them across time and different websites. However, privacy-conscious consumers can make use of various privacy means to control the degree of persistence of this identifier. The primary means available to them are browser-based tools, such as manually deletion of cookies, “private browsing” mode, or cookie blockers. These browser-based privacy means regenerate the cookie identifier but the data that is generated on the website is still sent and stored. The data is attributed to different consumers, even though they originate from the same consumer.

The GDPR opt-in rule provides another way for consumers to protect their privacy. The stipulations of GDPR, properly implemented and utilized by consumers, arguably provide a stronger protection than the aforementioned means since they block all non-essential information from being sent to the third-party website. In our context, consumers should always have the option to opt out of having their data sent to the intermediary since it provides a non-essential, third-party service.

An important distinction for our purposes is, therefore, that browser-based privacy means do not prevent a consumer’s data from being sent to the website and only give consumers control over the website’s identifier. The consent requirement of GDPR goes one step beyond that and enables consumers to deny any data to be sent to the website. As a result, substitution between these two can lead to a different data generating process. Browser-based privacy means lead to many artificially short consumer histories, whereas GDPR opt-out simply removes the data.

---

12 Common alternatives are other forms of storage in the browser as well as device fingerprinting, which use Internet Protocol (IP) addresses combined with device specific information to identify individuals. However, these are less commonly utilized and importantly not utilized by the intermediary.

13 Private browsing modes create “sandbox” browser environments where cookies are only set and used for the duration of the private browsing session. As a result, the website cannot link together data from the same consumer both before and after the private browsing section.

14 There also exist industry opt-out services, such as the Ad Choices program, but these are relatively hard to use and have little usage (Johnson, Shriver and Du, 2020). Survey-based evidence informs us that the most utilized privacy means by consumers is manual cookie deletion (Boerman, Kruikemeier and Zuiderveen Borgesius, 2018).

15 It is important to note that GDPR does not prevent “essential” information from being sent to a website. For instance, the ability to store consumer session cookies that allow them to provide a consistent consumer experience for the consumer may be considered “essential” information. The intermediary that we partner with, however, is a third-party service that provides complementary services to the primary functioning of the websites and so is not an “essential” service on any website where we observe data. As a result, any usage of GDPR opt-out shuts out data from being sent to the intermediary.
This is illustrated in Figure 2. The figure shows the data that is generated by four different consumers. “Full Visibility Baseline” shows a hypothetical scenario where each of the four consumers is fully identifiable. They generate spells of browsing sessions where each dot corresponds to one session and the color of the dot indicates whether or not the consumer purchased a good on the website as a result of that search. Suppose that only consumer four is privacy-conscious. Before GDPR, consumer four can protect her privacy by deleting her cookies and regenerating her identifier. This is illustrated in the second panel of the figure where the two sessions for this consumer are associated with two separate identifiers from the perspective of the intermediary. However, the third panel shows that, when GDPR opt-out is available, this consumer opts out and their data completely disappears.

The figure also illustrates how the different data scenarios impact consumer predictability and how the privacy choices of individuals lead to informational externalities. The intermediary’s objective is to predict the probability that an identifier will purchase the next time that she appears on the website. The intermediary has available the full history associated with the identifier so that she can design a prediction rule that depends on how many times this identifier has

---

Notes: The leftmost column displays the identifier observed by the intermediary. The left panel represents the scenario where the behavior of each consumer is fully observable. The middle panel shows how, before GDPR, the privacy conscious consumer 4 has her identifier partitioned into two separate identifiers from the perspective of the intermediary. The right panel shows how, under GDPR, the data of the privacy conscious consumer, is not directly sent to the intermediary.

16It’s important to point out that consumers can still make use of both privacy means and do not necessarily need to substitute from exclusively using browser-based privacy means towards exclusively using GDPR-provided privacy means. However, from the perspective of the intermediary and websites in general, once a consumer utilizes GDPR opt-out then, since they no longer see any data from this consumer, the browser-based privacy means become irrelevant. As a result, from their perspective, it appears as a direct substitution.
appeared on the website and how often this has resulted in purchase. Under full visibility, each consumer has a distinct search and purchase history so that the intermediary gets a distinct signal and can adjust its prediction rule accordingly. However, under obfuscation, consumer four deletes her cookies and gets partitioned into two separate identifiers. Now the consumer history associated with identifier 4 is identical to that of identifier 1 and the consumer history associated with identifier 5 is identical to that of identifier 2. Thus, the ability of the intermediary to predict the behavior of consumers 1 and 2 is affected by the privacy protection employed by consumer 4 as, even though their histories are not the same, they appear so to the intermediary. Under GDPR, on the other hand, consumer 4’s data is not observed at all. While this leads to a loss in the amount of data, it removes the externality that consumer 4 imposed on consumer 1 and 2 that occurred under obfuscation and improves the ability of the intermediary to predict their behavior.

3 Data and Empirical Strategy

We obtained access to a new and comprehensive dataset from an anonymous intermediary that records the entirety of consumer search queries and purchases across most major online travel agencies (OTAs) in the United States and Europe as well as most prominent travel meta-search engines from January 1st, 2018 until July 31st, 2018. We observe consumer searches, online advertising, the intermediary’s prediction of consumer behavior, and consumer purchases.

3.1 Data Description

The disaggregated data contains each search query and purchase made on these platforms as well as the associated advertising auction for each query. In a single search query the data contains: the identifier of the consumer, the time of the query, the details of the query (i.e. travel information), an identifier for the platform, the browser, the operating system, and the estimated probability of purchase on the website according to the predictive machine learning algorithm employed by the intermediary. For a subset of the websites, we observe purchase information containing the consumer identifier and time of purchase.

Each query can trigger an advertising auction. In that case, the data contains: the number of bidders in the auction, the values of the winning bids, and an identifier for the winning bidders. Furthermore, if a consumer clicks on the resulting advertisement, the click itself and the resulting transfer between the advertiser and the intermediary are recorded.

Our analysis utilizes an aggregation of this dataset by week, operating system, web browser, website identifier, and country. The data was aggregated on a weekly level to remove unimportant
day-of-the-week fluctuations. Further, the GDPR compliance date was May 25th, 2018, which was on a Friday and, as a result, our data was aggregated on a Friday-to-Friday level. Note that the GDPR compliance date corresponds to the beginning of the 22nd week in the year according to our labeling.17

### 3.2 Empirical Strategy

To understand the causal effect of GDPR we rely on a difference-in-differences design that exploits the geographic reach of the EU GDPR regulation. The regulation stipulates that websites that transact with EU consumers were required to ask consumers for explicit consent to use their data through an opt-in procedure, while those who processed non-EU consumers data were not obligated to do so. Even though many online travel companies transact with consumers in several countries around the world this specification works well in our setting since it is common for online travel websites to have separate, country-specific, versions of their websites and only the websites intended for EU countries are made GDPR compliant.

Our analysis focuses on the effect of the overall policy and not the effect of specific implementations of the policy. Thus, the treatment date of the policy corresponds to the GDPR compliance date, which was May 25th, 2018 (or the beginning of week 22). Our treatment group consists of nearly the universe of travel websites in major EU countries (at the time): Italy, the United Kingdom, France, Germany, and Spain. Our control group consists of nearly the universe of travel platforms in the United States, Canada, and Russia. These countries were chosen as controls since EU laws do not directly apply to them, but their seasonal travel patterns are similar to those in the EU countries as a result of similar weather and vacation patterns throughout the year.

Our primary regression specification is the following for the outcome variables of interest where $c$ denotes country, $j$ denotes the website, $o$ denotes operating system, $b$ denotes web browser, $p$ denotes product type (hotels or flights), and $t$ denotes the week in the year:

\[
y_{tcjobp} = \alpha_t + \delta_{jc} + \gamma_o + \zeta_b + \omega_p + \beta(EU_j \times after) + \epsilon_{tcjobp}
\]

(1)

$EU_j$ denotes a website subject to the regulation, $after$ denotes whether the current week is after the GDPR compliance date (i.e. week 22 or later), $\alpha_t$ denotes time fixed effects, $\delta_{jc}$ denotes country-specific website fixed effects, $\omega_p$ denotes product type fixed effects, $\gamma_o$ denotes operating system fixed effects, and $\zeta_b$ denotes browser fixed effects. Our standard errors are clustered at the

---

17Note that we further enforce a balanced panel by dropping any observation that has zero logged searches in any period during our sample period. We do this in order to ensure that our results are not biased from entry / exit of websites into our data during the sample period, which would bias our estimates. According to discussions with our data provider, this entry and exit is usually a result of varying contractual relations between the intermediary and the websites and so is largely orthogonal to our variables of interest.
In order to validate parallel trends and to understand the persistence of the treatment effect, we further utilize a regression specification that captures the potentially time-varying nature of the treatment:

$$y_{tcjobp} = \alpha_t + \delta_{jc} + \gamma_0 + \zeta_b + \omega_p + \sum_{k=T}^{T} \beta_k EU_j + \epsilon_{tcjobp}$$ (2)

The variable definitions are the same as before and we similarly cluster our standard errors at the website-country level.

We run our regressions over the time period between weeks 16 and 29 of 2018, which is between April 13th and July 20th. The GDPR compliance date aligns with the beginning of week 22. Further, week 20 is consistently the baseline week in our regressions since there are some firms that began to implement GDPR near the end of week 21 and so week 20 is the last week where there should be no direct impact from GDPR as a result of website implementation.$^{18,19}$

Our empirical strategy centers around the official GDPR implementation date. However, each website had to individually implement the changes stipulated by GDPR and there is evidence that there was considerable heterogeneity in compliance among firms. Further, even within the subset of firms that complied with the regulation, the degree to which consumers responded varied considerably based on the nature of implementation (Utz et al., 2019). As a result, we would want to include information on the timing and degree of implementation across the various websites in our sample. However, due to technical limitations, we cannot directly observe the timing and degree of GDPR implementation during the time period we study.$^{20}$

Thus, any effects that we observe with our empirical specification are a combination of the explicit consequences as a result of implementing the stipulations of GDPR for the subset of websites that implemented it and any changes in advertiser and consumer behavior in response

---

$^{18}$Our dataset ends on July 31st, 2018, which is a Tuesday, and an important measure that we want to track is the amount of consumer persistence on a weekly level, which looks at the fraction of observed cookies that remain observable in the data after some number of weeks. Since this measure requires a complete week of data to compute properly, we drop the incomplete week at the end of July as well as the full last week in July so that we can have consistency between the regressions on aggregate consumer response and those on consumer persistence.

$^{19}$Our analysis ends at the end of July since this was the time period over which we were able to obtain data from our data provider.

$^{20}$We attempted to utilize tools such as the Wayback Machine, which takes snapshots of websites across the entire Internet frequently. However, the coverage of relevant websites on the Wayback Machine is spotty and, given that many of the consent dialogs for GDPR consent are dynamically generated, are not always picked up by the snapshot taken of the website.
to the increased saliency of privacy considerations on the Internet\textsuperscript{21,22}. Thus, since we do not observe the full extent of non-compliance, our estimates can be viewed as a lower bound on the true impact of the policy had websites all fully complied with it.

4 Consumer Response to GDPR

In this section we quantify the extent to which consumers utilize the GDPR-mandated ability to opt out. We measure how GDPR opt-out impacts the total number of cookies and searches observed by the intermediary. We then explore whether there were any changes in the composition of the remaining, opted-in consumers.

4.1 Opt-Out Usage

Recall that we do not directly observe opt-out in our dataset because consumers who opt out are no longer part of our dataset. As a result, at time $t$, the total number of consumers on a website $j$ is given by the true number of consumers subtracted by the number of consumers who have opted out.

\begin{equation}
U_{jt}^{OBS} = U_{jt}^{TRUE} - U_{jt}^{OPT-OUT}
\end{equation}

In the control group, $U_{jt}^{OPT-OUT} = 0$, whereas post-GDPR $U_{jt}^{OPT-OUT} \geq 0$. We assume parallel trends in $U_{jt}^{TRUE}$, which means that any change in $U_{jt}^{OBS}$ allows us to identify $U_{jt}^{OPT-OUT}$\textsuperscript{23,24}.

Figure 3 displays the total unique cookies for two multi-national websites, one of which appears to have implemented the consent guidelines of the GDPR and the other which did not.

\textsuperscript{21}It would be interesting to isolate the effects of each possible channel, though our data limitations prohibit us from doing so. We were able to verify that several websites in our sample implemented GDPR consent guidelines around the time of the policy and that several websites in our sample did not, though there are a considerable number for which we are uncertain when they implemented the policy.

\textsuperscript{22}Another complication is that the Cambridge Analytica scandal was salient in the news cycle in the United States in early May 2018, which may have lead to heightened privacy concerns amongst U.S. consumers. If anything, this would lead our empirical strategy to under-estimate the size of the impact.

\textsuperscript{23}As noted in Goldberg, Johnson and Shriver (2019), another possible complication is that this could be a result of firms changing the type of data that they send to third party services. To our knowledge there is no change in the data the websites send to the intermediary as a result of GDPR since the intermediary and the data are crucial for generating advertising revenue for these websites. Further, if a website decided to stop using the intermediary altogether then, as noted previously, they would not be part of our sample.

\textsuperscript{24}Another possible confounding factor is the sales activity of the intermediary. For instance, it’s possible for the intermediary to sell additional advertising units to a website that can appear on pages of the website where the intermediary previously was not tracking before. If there was a differential effect from this around the date of the treatment then this could systematically bias the number of unique cookies and searches that we observe. To test the plausibility of this hypothesis, we run our difference-in-differences specification with these outcome variables with the results in Table 5 showing that there was no significant change. Thus, we rule out this as a possible explanation.
The multi-national website which appears to have implemented the consent guidelines shows a clear drop in observed cookies on European websites at the onset of GDPR. Columns (1) and (2) of Table 1 report the result of regression (1) with total number of observed unique cookies as the outcome variable. We consider the specification in both levels and logs. The estimates show that, in aggregate, GDPR reduced the total number of unique cookies by around 12.5%. As previously mentioned, our estimates should be interpreted in the context of mixed compliance with the consent guidelines of GDPR as evidenced from Figure 3.

It is important to note that this result does not imply that 12.5% of consumers made use of the opt-out features. This is because the unit of observation is a cookie, rather than a consumer. A single consumer can appear under multiple cookie identifiers if they make use of the aforementioned browser-based privacy means. Nonetheless, the results point to a relatively large usage of the opt-out features by consumers.

Another measure of consumer response is the total number of searches that is recorded by the intermediary. We re-run the same specification with recorded searches as the dependent variable and report the results in columns (3) and (4) of Table 1. We find that there’s a 10.7% drop in the overall recorded searches which is qualitatively consistent with the effect size of the specification using the number of unique cookies.

In order to demonstrate the validity of the difference-in-differences estimates for both of these outcome variables, we provide evidence that the parallel trends assumption holds in our setting by estimating the time-varying treatment specification (2). Figure 8 displays the resulting treatment effect over time and points to parallel trends being satisfied as well as a consistent treatment effect size over our sample period. Furthermore, Figure 3 provides evidence that, even for multi-national publishers which one might worry will have spillovers between the treatment and control groups, parallel trends appears to hold.
Notes: A single point on the graph represents the total number of unique cookies for a single country, reported in terms of its percent deviation relative to week 20, or \( \frac{U_t - U_{t=20}}{U_{t=20}} \), \( \forall t \neq 20 \). The figure on the left presents a multi-national publisher that appears to have implemented the consent guidelines of GDPR. In this figure, the black dots represent the represented European countries (United Kingdom, France, Germany, Italy, Spain) and the two white dots represent the two non-EU countries where this website functions - the United States and Canada. The figure on the right presents a multi-national publisher that appears to not have implemented the consent guidelines of GDPR. The black dots represent the values from the United Kingdom and the white dots represent the values from the United States.

Notes: t-statistics are reported in parentheses. The standard errors for every regression are clustered at the website-country level. We aggregate every dependent variable to the website-country-product type-week level between weeks 16 and 29, including both weeks 16 and 29 (April 13th - July 20th). The dependent variables in the regression reported in the first and second column are the log and overall level of the number of unique cookies observed. The dependent variables in the regression reported in the third and fourth column are the log and overall level of the number of total recorded searches.
4.2 Persistence of Identifier

A natural question is whether there were any changes in the composition of the remaining consumers who did not opt out. Our primary measure for investigating this is by tracking the average persistence of a consumer identifier before and after GDPR. We define an identifier persistence measure that tracks how often cookies that we see in a given week return after $k$ weeks, where we explore different values for $k$ (1,2,3, and 4 weeks). Let $C_{jt}$ be the set of cookies seen in week $t$ on website $j$, the measure is then given by:

$$
persistence_{kt} = \frac{|C_{jt} \cap C_{j,t+k}|}{|C_{jt}|}
$$

In Figure 4 we set $k = 4$ and display the persistence measure for the same two multi-national websites with country-specific versions of their website over time. At the onset of GDPR there is a clear increase in persistence on the EU-based websites, but no noticeable difference in the non-EU websites for the website which appeared to have implemented GDPR guidelines and suffered a loss in overall cookies. However, there does not appear to be much of a change for the website which did not implement the consent guidelines from the previous figure. We further validate this increase by running our baseline difference-in-differences specification using the persistence outcome variable for $k \in \{1, 2, 3, 4\}$.²⁵,²⁶

Table 2 shows the results of this regression, which indicate that there is a statistically significant and meaningful increase in consumer persistence and that this effect gets more pronounced as $k$ increases.²⁷ We further run the time-varying treatment specification (2) in order to validate that parallel trends holds and to understand the consistency of the effect over time. Figure 9 shows that while for $k = 1$ the time dependent treatment effects are more noisy, for all $k \geq 2$ parallel trends hold and the treatment effect is stable over time.²⁸

The treatment effect remains roughly the same as $k$ grows, even though Table 6 shows that the mean persistence declines as $k$ increases. For instance, in the pre-treatment period, the mean persistence for EU websites was 0.0597 and the estimated treatment effect is 0.005 indicating a roughly 8% increase in persistence.

²⁵In order to run specification (1) we drop the last 4 weeks of our sample so that we are utilizing the same sample as we vary $k$. However, our results are qualitatively robust to including these weeks when the data for them is available.

²⁶Note that the units on the regression and Figure 4 are not the same. Figure 4 displays the persistence measure in terms of percent deviations from week 20 whereas the coefficients in Table 2 are changes in levels.

²⁷It is important to note that the persistence measure may have some noise when $k = 1$ due to consumer activity near the end of the week that spills over into the next week and falsely appears as persistence. As a result, the most reliable measures of consumer persistence are for $k \geq 2$, but we report $k = 1$ for completeness.

²⁸Further, Figure 10 in the appendix shows the overall distributions of consumer persistence for the EU vs. non-EU and note that there are some outliers. In particular, there is a large mass of high persistence observations and persistence measures close to 0. Our results are qualitatively robust to running our specifications winsorizing and dropping these observations as well.
Figure 4: Four Week Persistence for Two Multi-National Websites

Notes: A single point on the graph represents the four week persistence fraction for a single country, reported in terms of its percent deviation relative to week 20, or $\frac{\text{persistence}_{4,t} - \text{persistence}_{4,t=20}}{\text{persistence}_{4,t=20}}$ $\forall t \neq 20$. The figure on the left presents a multi-national publisher that appeared to implement the consent guidelines of GDPR. In this figure, the black dots represent the represented European countries (United Kingdom, France, Germany, Italy, Spain) and the two white dots represent the two non-EU countries where this website functions - the United States and Canada. The figure on the right presents a multi-national publisher that appears to have not implemented the consent guidelines of GDPR. The black dots represent the values from the United Kingdom and the white dots represent the values from the United States.

Notes: t-statistics are reported in parentheses. The standard errors for every regression are clustered at the website-country level. We aggregate every dependent variable to the website-country-product type-week level between weeks 16 and 26, including both weeks 16 and 26 (April 13th - June 29th). The dependent variables in the regression are the consumer persistence measures for $k = 1, 2, 3, 4$, respectively.
The economic implications of the increase in persistence depend on the mechanisms that drive this effect for which we have two plausible hypothesis. The first is a *selective consent hypothesis* where consumers only consent to data processing by websites that they frequently use. Under this hypothesis, if infrequent users of a website are those who deny consent to data storage more-so than frequent users, then the remaining set of consumers will naturally appear to be more persistent. The second is a *privacy means substitution hypothesis* where privacy conscious consumers who were previously making use of browser-based privacy means now utilize GDPR opt-in to protect their privacy. Recall that the utilization of these privacy means would result in many artificially short-lived consumers. If these same consumers utilize GDPR opt-in instead they would no longer show up in the intermediary’s dataset and the remaining set of consumers would appear to be more persistent even though their true search and purchase behavior may not have changed.

If the selective consent hypothesis is the predominant explanation for the increased persistence, then privacy regulation may favor firms with more established reputations or offer a wider variety of services. The hypothesis would imply that in the long run consent for data collection can serve as a barrier to entry for newer firms with less established reputations and a smaller variety of services.

If the privacy means substitution hypothesis is the predominant explanation for the increased persistence, then there are several economically relevant consequences. First, the benefit of GDPR would be the marginal effect over existing privacy protection. Thus, even though a significant fraction of consumers exercised their ability to opt out of data collection, the welfare gains for the opted out consumers may be low if the marginal privacy gain relative to these pre-existing means is low. Second, the usage of GDPR opt-out would lead to an externality on the opt-in consumers and, as a result, their privacy protection may be weakened. This would directly mean that firms relying on prediction may not suffer as much as the number of opt out indicates since this would enhance their prediction capabilities. Finally, it would allow for better advertisement attribution and measurement of advertising effectiveness which would directly influence the price advertisers are willing to pay for advertising.

We further study the overall distribution of consumer searches before and after GDPR. Figure 5 shows that only the probability mass of single searchers seems to have dropped and the shift in probability mass seems to be roughly evenly distributed across the different number of searches. This provides strong evidence that, at least for this site, the increase in persistence is largely driven by the drop in the “single searchers” which is consistent with what we would ex-

---

29There is a connection of this hypothesis to the theoretical predictions in Campbell, Goldfarb and Tucker (2015), who argue that consent-based data collection practices would allow larger firms to collect more data than smaller firms since they offer a wider scope of services. As a result, consumers may utilize these websites more and trust the website with their data more.
Figure 5: Change in Search Distribution for One Site

Notes: The figure on the left shows the difference in the share of consumers with \( x \) searches in the full sample after GDPR compared to before GDPR. For instance, the leftmost point indicates that there was a roughly 12.8% decrease in the share of cookies associated with a single search. The figure on the right breaks down the share of cookies associated with only one search week by week, as opposed to pooling the full sample periods before and after GDPR.

We now study the effect of GDPR on the market for online advertising. Specifically, we investigate the extent to which consumer opt-out and increase in average trackability affected advertiser’s average value of consumers and overall revenue for both advertisers and websites. To be clear, opt out consumers drop out of the intermediary’s reach and are never shown any advertisements. Thus, the intermediary generates no advertising revenues from these consumers. Advertisements

5 GDPR and Online Advertising

We now study the effect of GDPR on the market for online advertising. Specifically, we investigate the extent to which consumer opt-out and increase in average trackability affected advertiser’s average value of consumers and overall revenue for both advertisers and websites. To be clear, opt out consumers drop out of the intermediary’s reach and are never shown any advertisements. Thus, the intermediary generates no advertising revenues from these consumers. Advertisements
are sold via real-time auctions that are held after a consumer makes a search query. Advertisers
bid on search keywords such as the origination, destination, or dates of travel. For example, an
advertiser may submit a bid to show an advertisement for a consumer searching for flights on a
particular route and the resulting advertisement that gets shown is a price comparison advertise-
ment for this particular route and dates. Thus, any changes in advertiser behavior would result
from changes in their overall estimate of the value of consumers. Bids are submitted per click
and a payment from the advertiser to the intermediary only occurs if the consumer clicks on the
advertisement.

First, we use a difference-in-differences specification to investigate whether the drop in unique
identifiers and searches was associated with a similar drop in the total number of advertisements
served. Table 9 shows a drop in the number of advertisements, but the drop is not statistically
significant. Figure 11 shows the time varying treatment effect, which confirms this pattern. This
shows that the drop in advertisements shown is not as stark as the drop in unique cookies and
recorded searches.

We next examine the effect on overall revenues earned by websites and advertisers. Revenues
depend both on the number of clicks as well as the price per click. Columns (1) - (2) of Table 3
show that there is a statistically significant decrease of 13.5% in the total number of clicks, with
an effect size commensurate with the drop in total cookies and searches. Furthermore, we look
for changes in the number of distinct cookies associated with a click to see if any changes were
driven by some small set of consumers who drive advertising revenues. Columns (3) - (4) show
that the number of distinct clicks also decreases significantly. Finally, Figure 6 displays the time-
varying specification for these outcome variable and shows that the effect on the number of clicks
is relatively constant after the GDPR implementation date.

Columns (5) and (6) of Table 3 provide the estimate of the impact on revenue. The mag-
nitude of the point estimates suggests an economically significant drop, though it is imprecise
and not statistically significant. The time-varying treatment effect displayed in Figure 6 shows
that revenue initially falls sharply after the implementation of GDPR and then begins to recover.
Importantly, column (7) of Table 3 shows that the average bid of the advertisers increases. This
increase is economically significant as it points to a roughly 11.9% increase in the average bid
relative to pre-GDPR levels. We interpret this as an increase in the perceived average value that
advertisers place on remaining consumers after GDPR.\footnote{Note that in order to preserve the privacy of our intermediary, the bid and revenue values are obfuscated by a common multiplier. However, the interpretation of percentage changes is preserved under this transformation.}

\footnote{The auction format is a linear combination of a generalized first and second price auction where there are \( N \) advertisers and \( k \) slots.}

\footnote{This relationship is not necessarily mechanical since the individuals who opt out may differ on other dimensions, such as their propensity to click on advertisement and purchase.}

* p < 0.10, ** p < 0.05, *** p < 0.01

Notes: t-statistics are reported in parentheses. The standard errors for every regression are clustered at the website-country level. We aggregate every dependent variable to the website-country-product type-week level between weeks 16 and 29, including both weeks 16 and 29 (April 13th - July 20th). The dependent variable in the regression reported in the first column is the total number of clicks associated with each observation and the second column is the inverse hyperbolic sine transform of this value. Likewise, the dependent variables in the third and fourth columns are the total number and inverse hyperbolic sine transform of the total number of unique cookies who interacted with advertisements. The dependent variables in the fifth and sixth column are the total number and inverse hyperbolic sine transform of the total revenue. The dependent variable in the seventh column is the average bid by advertisers. We utilize the inverse hyperbolic sine transform instead of the logarithm as in previous sections as some of the outcome variables we consider in this section can take zero values. The inverse hyperbolic sine transform is given by $g = \text{arcsinh}(y) = \ln(y + \sqrt{y^2 + 1})$ and results in a similar coefficient interpretation as taking logarithms (Bellemare and Wichman, 2019), but does not remove the zero valued observations from the data. We retain the zero values here so that there is a clearer comparison between the estimates before and after the transformation.
Figure 6 displays the time-varying coefficient for the average transfer for a consumer and shows that the transfer does not change initially after the policy and then increases gradually. As a result, the immediate drop in clicks following GDPR leads to an immediate drop in revenue, but the increase in the average transfer for consumers after GDPR leads to a recovery of some of the lost revenue for the intermediary and advertisers.

We now explore the mechanisms behind the increase in bids for consumers. One possibility is that just as GDPR was implemented there was also a change in the composition of advertisers. Advertisers could have have entered or exited from the European market as a result of GDPR or for other unrelated reasons. In order to explore whether this was the case we compute the share of winning bids for each advertiser and track any changes in market concentration. We compute the two most commonly utilized market concentration measures: Concentration Ratio and the Herfindahl-Hirschman Index. We utilize our previously defined specifications to see whether there was any change in market concentration. The details of this exercise are described in Appendix D. We find a statistically significant but economically small increase in bidder concentration. Increased concentration in advertisers should have decreased the prices, not increased them. Therefore, we conclude that changes on the demand side are likely not the reason for the observed price increase.

Another explanation is that advertisers’ bids are determined by their marketing budgets rather than their valuation of consumers’ clicks. As a result of the reduction in advertisements served, advertisers may simply be allocating more of their budget towards individual advertisements, driving up the average bid. However, while our data does not allow us to directly observe advertisers’ budgets, we can reject this explanation. Advertisers set a daily budget and so if this were the predominant explanation then we would observe a corresponding sudden increase in the average bid as the number of advertisements served suddenly decreased. However, Figure 6 shows that the increase in average bid is gradual and only begins to increase several weeks after the drop in advertisements served and clicks.

A more plausible explanation relates directly to the result that remaining consumers are now more trackable and therefore advertisers are better able to attribute purchases to advertisements. Advertisers assess the value of a consumer based on the conversion rate of an advertisement, which is the fraction of consumers that end up purchasing a good after clicking on an advertisement. However, effective measurement requires that the advertiser and intermediary can attribute purchases to advertisements, which relies on their capability to track consumers across time and websites.
Figure 6: Week by Week Treatment Effect for Total Clicks, Revenue, and Average Transfer
For instance, if a consumer deletes her cookies after clicking the advertisement and then subsequently purchases a good, the advertiser and intermediary will not be able to attribute the advertisement to a purchase. An implication of this is that consumers that are utilizing browser-based privacy means bias the perceived value advertisers have of consumers downwards. If the consumers that are utilizing these privacy means alternatively utilize the privacy means offered by GDPR instead, they will not appear in the sample of the advertisers whatsoever, which will lead the advertisers to gradually increase their perceived value of consumers.

As an illustrative example, suppose that there are five consumers who click on an advertisement. Suppose one of them (from hereon consumer A) deletes her cookies but ends up purchasing and, from the remaining four, suppose two of them end up purchasing. Thus, regardless of the behavior of consumer A, the advertiser’s estimated conversion rate is 0.4, which is only correct in the case where consumer A never purchases. Suppose, instead, that GDPR opt-out is available and consumer A is removed from the sample of the advertiser and therefore never clicks on an advertisement. The advertiser’s estimated conversion rate is 0.5 now, as opposed to 0.4 and so the perceived value of consumers weakly increases irregardless of consumer A’s true behavior. More generally, dropping individuals similar consumer A from the observed sample can only weakly increase the advertiser’s perceived value.

The changes that we observe in the advertising market are, therefore, consistent with the observation in Section 4. These results strongly suggest that GDPR has made it easier for advertisers to assess the value of consumers by improving their ability to track them and measure the effectiveness of advertisements.

6 GDPR and Prediction of Consumer Behavior

In this section we investigate whether the changes due to GDPR have affected the intermediary’s ability to predict consumer behavior. Based on our analysis we expect there to be three predominant reasons why we might observe a change in the ability to predict. First, GDPR has significantly reduced the overall amount of data. Second, remaining consumers have longer histories and are more trackable. Third, in line with our illustration in Figure 2, GDPR might reveal correlation structures between between consumer behavior and the length of consumer histories that were previously obfuscated by the use of alternative privacy tools. We would expect the first effect to decrease predictive performance and the second and third to increase predictive performance.

We take as given both the setup of the prediction problem and the algorithm that the intermediary uses. This allows us to understand the effects of GDPR on the prediction problem “in the field.” Its problem is to predict whether a consumer will purchase from a site she visits based on
history that the intermediary observes about this consumer. Specifically, its algorithm classifies a search by a consumer into two categories: *purchasers* and *non-purchasers*, based on whether the consumer will purchase a product on the current website *within some time window*. Formally, each query is classified into

\[
y_{ijk} = \begin{cases} 
1, & \text{if } i \text{ is a purchaser on website } j \text{ after search } k \\
0, & \text{if } i \text{ is not a purchaser on website } j \text{ after search } k,
\end{cases}
\]

for a cookie \(i\) on website \(j\) on the \(k\)th query observed by the intermediary. For every cookie \(i\) we observe a series of searches on website \(j\), \(X_{ij1}, X_{ij2}, ..., X_{ijn}\) and, if the consumer ended up making a purchase on this website, the time-stamp of when consumer \(i\) purchased on website \(j\). For every \(X_{ijk}\) that we observe, \(y_{ijk} = 1\) if the purchase occurs within \(N\) days of the query and \(y_{ijk} = 0\) otherwise. While in practice the value of \(N\) is platform-dependent, for our analysis we restrict focus to \(N = 2\).

We will denote the *class proportion* as the proportion of searches that are associated with the purchaser class.

For each search, the intermediary produces a probability estimate that the consumer is a purchaser:

\[
p_{ijk} = \Pr(y_{ijk} = 1 \mid X_{ij1}, ..., X_{ijn}), \forall i, j, k
\tag{3}
\]

We observe the intermediary’s predicted \(\hat{p}_{ijk}\) for every search.

In practice, for its own operation, the intermediary classifies each consumer into the two groups in real time during each search. This determination is based on whether the consumer’s “score” \(\hat{p}_{ijk}\) is above or below a chosen threshold \(\hat{P}\).

### 6.1 Prediction Evaluation Measures

To evaluate the performance of the classifier deployed by the intermediary, we use two standard measures from the machine learning literature: the *Mean Squared Error (MSE)* and *Area under the ROC Curve (AUC)*.

---

33For the majority of websites in our sample the intermediary sets \(N = 1\) or \(N = 2\). Further, from our preliminary analysis, the results do not qualitatively differ between \(N = 1\) and \(N = 2\).

34The value of this threshold is determined by revenue considerations and other factors irrelevant to the quality of predictions. As a result, we restrict focus on the probabilistic estimate \(\hat{p}_{ijk}\) and not the actual classification.

35Ferri, Hernández-Orallo and Modroiu (2009) and Hernández-Orallo, Flach and Ferri (2012) provide a comprehensive analysis of classification evaluation metrics and differentiate between three classes of evaluation metrics. (1) Metrics based on a threshold that provide an error rate on actual classifications as opposed to predicted probabilities. (2) Metrics based on a probabilistic interpretation of error, which capture the difference between the estimated and true probabilities. (3) Metrics based on how the classifier ranks the samples in terms of likelihood to be a purchaser as opposed to a non-purchaser. As mentioned previously, we ignore the first class of metrics since there are idiosyn-
The MSE computes the mean of the squared errors associated with the predicted estimate \( \hat{p}_{ijk} \) relative to the realized binary event. Specifically, let \( I_j \) be the set of all consumers on website \( j \) and let \( K_{ij} \) be the set of all events for consumer \( i \) on website \( j \). Then, the MSE of website \( j \) is given by,

\[
MSE_j = \frac{1}{\sum_{i \in I_j} |K_{ij}|} \sum_{i \in I_j} \sum_{k \in K_{ij}} (\hat{p}_{ijk} - y_{ijk})^2,
\]

with a low MSE indicating a good prediction performance.

Although commonly used, the MSE has a couple of drawbacks for the current purpose. First, the measure is sensitive to the skewness of, and the change in, the class distribution. In the current context, about 90% of the searches result in non-purchase, which means that the estimate \( \hat{p}_{ijk} \) tends to be low; intuitively, the estimate would tolerate more errors associated with the “infrequent” event (purchase) in order to minimize the errors associated with the more “frequent” event (non-purchase). Suppose now the class distribution changes so that more searches result in purchases. This is indeed what happens in our data after GDPR. Then, even though the consumer may not have become less predictable, MSE would rise artificially, due to the convexity associated with the formula, especially if the prediction algorithm does not adjust to the change in the distribution. Second, perhaps not unrelated to the first issue, the MSE is not the measure that the intermediary focuses on for its operation as well as for communicating with its partners. Instead, it focuses on AUC (the area under the curve), which we now turn to.

The AUC measures the area under the Receiver Operating Characteristic (ROC) curve.\(^{36}\) The ROC curve in turn measures how well the classifier trades off Type I (“false positive”) with Type II (“false negative”) errors. To begin, fix the classification threshold at any \( \hat{P} \). Then, a consumer with score \( \hat{p}_{ijk} \) is classified as a purchaser if \( \hat{p}_{ijk} > \hat{P} \) and a non-purchaser if \( \hat{p}_{ijk} < \hat{P} \). This would result in a false positive rate—a rate at which a non-purchaser is misclassified into a purchaser:

\[
FPR := \frac{\text{False Positive}}{\text{True Negative} + \text{False Positive}} = \frac{\sum_{ijk} |\{\hat{p}_{ijk} > \hat{P}, y_{ijk} = 0\}|}{\sum_{ijk} |\{y_{ijk} = 0\}|}.
\]

At the same time, it would result in a true positive rate—or a rate at which a purchaser is correctly

---

\(^{36}\)For an extended discussion of ROC analysis, see Fawcett (2006).
Notes: This figure depicts an ROC curve, which maps out the trade-off between type I and type II errors for a classifier as the classification threshold varies. The area under the ROC curve is denoted by AUC and provides a scalar measure of prediction performance.

classified as a purchaser:

\[
TPR := \frac{\text{True Positive}}{\text{True Positive} + \text{False Negative}} = \frac{\sum_{ijk} \left\{ \hat{p}_{ijk} > \hat{P}, y_{ijk} = 1 \right\}}{\sum_{ijk} \left\{ y_{ijk} = 1 \right\}}.
\]

The ROC then depicts the level of \( TPR \) a prediction machine achieves for each level of \( FPR \) it tolerates.

The ROC is obtained by tracing the locus of \((FPR, TPR)\) by varying the classification threshold \( \hat{P} \). The slope of the ROC corresponds to the additional power (in rate) the prediction gains for an additional unit of type I error (in rate) it tolerates. For a random predictor, this slope would be one, and the ROC will be a 45 degrees line. A better than random predictor would produce an ROC which lies above that 45 degrees line. Figure 7 depicts a typical ROC curve.

The AUC, which measures the area under the ROC, provides a simple scalar measure of the prediction performance. If either the prediction technology improves or the consumer becomes more predictable, then the ROC will shift up and AUC will increase. Aside from the fact that the intermediary focuses on this measure, the AUC is invariant to the change in class distribution (Fawcett, 2006). Suppose for instance the proportion of purchasers increases, as long as the prediction technology remains unchanged, this does not alter FPR and TPR, so the ROC and AUC remain the same.

\[37\] For extreme cases, with \( \hat{P} = 1 \), all consumers are classified as non-purchasers, which yields \((FPR, TPR) = (0, 0)\), and with \( \hat{P} = 0 \) all consumers are classified as purchasers, which yields \((FPR, TPR) = (1, 1)\).
remain unchanged.

These two measures capture different aspects: AUC captures the ability for the classifier to separate the two different classes whereas MSE captures the accuracy of the estimated probabilities. Hence, we will report the effect on both since they provide two qualitatively different measures of prediction performance.

6.2 Prediction Performance

In this section we investigate the impact of GDPR on predictability at the immediate onset of its implementation. We utilize the same empirical strategy that we described in section 3. The same empirical design is valid because the intermediary trains separate models for each website using only the data from the respective website. As a result, any changes to the collected data from EU websites due to GDPR should not impact non-EU websites. However, there are two limiting factors in our analysis. The first is the restriction on the data; unlike the search and advertising data, the prediction performance requires additional purchase data, which is limited for only a subset of websites.\(^{38}\) The second is that the models are trained utilizing a sliding window of the data, which means that, even if there is a sudden change to the underlying data distribution, there may be a slow adjustment period that would vary across the different websites. As our analysis above shows, the pool of consumers has changed with GDPR. Our predictability regressions therefore compare the larger set of consumers before GDPR with a smaller set of consumers after GDPR. Changes in predictability are therefore a function of both the quantity of data and the selection of consumers where consumers with longer histories remain in the data.

Table 4 displays the difference-in-differences estimates for all of the relevant prediction related outcome variables. First, column (1) shows that GDPR results in a small but significant increase in the proportion of purchasers. Meanwhile, the insignificant coefficient for average predictive probability in column (2) shows that little adjustment by the classifier of the firm to this change. Figure 13 displays the time-varying specification for these outcome variables indicating that the average predicted probability remains constant whereas the class proportion fluctuates but appears to increase.

Columns (3) and (4) show the impact of GDPR on the prediction performance of the intermediary as measured in MSE and AUC, respectively. Column (3) shows a significant increase in MSE after GDPR. However, rather than indicating the worsened prediction performance, this is likely

---

\(^{38}\) We drop websites that either have no purchase data or where the class proportion is degenerate so that \(y_{ijkt} = 0\) or \(y_{ijkt} = 1\) for all cookies \(i\) on website \(j\). There are also two websites that we know had a reporting error for purchase data during our sample period and we drop them from our analysis. Further, we drop any \((\text{browser}, \text{OS}, \text{product}, \text{website}, \text{country})\) tuple that, on average, has fewer than 50 consumers a week since these observations are very noisy due to low sample sizes and the performance of the prediction problem is less interesting in these cases.
to be an artifact of the change in class proportion and the lack of adjustment by the classifier.\textsuperscript{39} Indeed, columns (5) and (6) show that MSE conditional on true class has not gone up; if anything, they have gone down albeit statistically insignificantly. As mentioned above, given the skewed distribution, an increase in the proportion of purchasers will raise the MSE. In fact, column (4) shows a positive estimate for the treatment effect on AUC indicating a marginal improvement in prediction, though it is not statistically significant. The marginal improvement in AUC indicates that, even in spite of the decreased accuracy of the estimated probabilities, the ability of the intermediary to separate the two classes has increased. This observation is consistent with what we would expect from the aforementioned hypothesis of privacy means substitution.

\* \(p < 0.10\), \** \(p < 0.05\), \**\* \(p < 0.01\)

Notes: t-statistics are reported in parentheses. The standard errors for every regression are clustered at the website-country level. We aggregate every dependent variable to the website-country-product type-week level between weeks 16 and 29 (April 13th - July 20th). The dependent variable in the regression reported in the first column is the proportion of purchasers associated with each observation and the second column is the average predicted probability. The dependent variables in the third and fourth column are the MSE and AUC, respectively. Finally, in the fifth and sixth columns the dependent variables are the MSE conditional on the true class of the observation.

Finally, Figure 14 displays the results from the time-varying specification for MSE and AUC, indicating that there was an initial increase in MSE followed by an eventual decline. This is consistent with the claim that much of the increase in MSE was a result of the lack of rapid adjustment. Further, the increases in AUC do not occur directly after GDPR but rather also occur gradually.

\textsuperscript{39} Appendix F decomposes the change of MSE to accounts for the extent to which the increase may have resulted from the classifier’s lack of rapid adjustment to the post-GDPR consumer distribution leading the estimated class probabilities to no longer as closely match the empirical class probabilities.
Overall, our results suggest that GDPR has not negatively impacted the ability to predict consumer behavior and if at all, the sign of the treatment effect suggests the opposite. This is further validated by the exercise in Appendix G which identifies the expected “long run” changes in prediction performance as a result of the changes to the data observed in section 4. This exercise shows that the increase in trackability ought to lead to marginal improvements to prediction performance, whereas the change in the overall size of data as a result of GDPR should not adversely impact prediction performance significantly.

7 Conclusion

In this paper we empirically study the effects of data privacy regulation by exploiting the introduction of GDPR as a natural experiment. We use data from an intermediary that contracts with many online travel agencies worldwide, which allows us to investigate the effect of GDPR on a comprehensive set of outcomes. Our analysis focuses on the stipulation of GDPR that requires firms to ask consumers for explicit consent to store and process their data.

Our results paint a novel and interesting picture of how a consumer’s privacy decision—particularly the means by which she protects her privacy—may impact the rest of the economy, including other consumers, and the firms and advertisers relying on consumer data. The strong and effective means of privacy protection made available by laws such as GDPR and the recent CCPA (California Consumer Privacy Act) should help the privacy-concerned consumers to protect their privacy by eliminating their digital footprints. These consumers are thus clear winners of the laws. However, the impacts on the others are less clear. Our results suggest the possibility that a consumer’s switching of the means of privacy protection makes the opt-in consumers who share their data more trackable and possibly more predictable to the firms with which they share data. If this increased identifiability makes up for decreased data (resulting from opt-outs), as indicated by Appendix G, then the firms using consumer data could also come out as winners. What about those consumers who opt in? Their welfare will depend on how their data is used by the firms. If their data is used to target advertising and services to their needs, they too could very well be winners of privacy laws, even if their decision to opt in may not have accounted for the externality. However, if their data is used for extracting consumer surplus, e.g., via personalized pricing, the externalities could harm them.

While these qualitative implications are clear, our reduced-form approach does not allow us to quantify the welfare implications for both consumers and advertisers. We leave for future work a structural analysis of the interactions that we identify in order to better understand the magnitude of each of the channels by which consumers and advertisers are affected. Given the large compliance costs associated with data privacy regulation, decomposing the welfare effects in this
manner is a fruitful direction for research and important for further building on our insights in order to guide the design and understanding the value of such regulation.

Finally, our paper has broader implications beyond the online travel industry and keyword-based advertising markets. Firms in this industry, as with many markets in the digital economy, increasingly compete with the large technology firms such as Google whose reach expands across many different online markets and for whom consumers have little choice but to accept data processing. As a result, while our results highlight that increased consent requirements may not be wholly negative for firms, if consumers are similarly using such opt-out capabilities at our estimated rates in other markets (such as behaviorally-targeted advertising markets) then another important direction for future work is understanding the extent to which such regulation puts firms in these markets at a disadvantage relative to these larger firms. We believe that these insights and directions for future work are useful for the design of the many proposed regulations in the US and around the world that follow in the footsteps of GDPR.

Figure 10: Distribution of Consumer Persistence (1 Week)
B Consumer Persistence Heterogeneous Treatment Effects

We further investigate the mechanisms behind the increased consumer persistence by estimating heterogeneous treatment effects across web browsers and operating systems. We exploit the fact that different browsers and operating systems attract different types of individuals with different levels of technical sophistication as well as provide different levels of privacy protection. This exercise provides additional evidence to disentangle the selective consent and privacy means substitution hypotheses since the selective consent hypothesis would predict that there should be no heterogeneity in persistence across these dimensions whereas the privacy means substitution hypothesis would predict the opposite.

First, we study heterogeneous treatment effects across web browsers and restrict attention to the most popular web browsers: Google Chrome, Microsoft Edge, Mozilla Firefox, Internet Explorer, Opera, and Apple Safari. We consider the following specification:

\[
y_{tcjobp} = \alpha_t + \delta_{jc} + \gamma_o + \zeta_b + \omega_p + \beta(EU_j \times after \times browser) + \epsilon_{tcjobp} \tag{5}
\]

There are two dimensions on which we could think that the differential change in persistence would vary across web browsers. The first is that there is a demographic selection into browsers and the ability to substitute between various privacy means requires technical sophistication (i.e. consumers need to know how to manage cookies). For instance, Internet Explorer (IE) is a web browser primarily used on older computers and is known to attract older, less technologically sophisticated, users. Thus, the privacy means substitution hypothesis seems more plausible if the effects are stronger on browsers with more technologically sophisticated consumers. The second is that there is different levels of privacy protection among browsers. For instance, Apple Safari at the time of the GDPR had a broad set of privacy protection means built into it, whereas Google Chrome had laxer privacy controls. As a result, we might expect that Safari users would value the privacy protection means offered by GDPR less and thus lead to a smaller increase in persistence.

Table 8 displays the regression results for this specification with Chrome as the omitted browser. The treatment effect is consistent across browsers with the exception of Internet Explorer which has almost no change in persistence. The estimated treatment effect is lower in Safari relative to Chrome, but not significantly so. This provides further evidence for the privacy means substitution hypothesis.

Next, we study heterogeneous treatment effects across operating systems and narrow down the sample to only look at the most popular operating systems: Android, Chrome OS, iOS, Linux, Mac OS X, and Windows. We consider the following specification:

\[
y_{tcjobp} = \alpha_t + \delta_{jc} + \gamma_o + \zeta_b + \omega_p + \beta(EU_j \times after \times OS) + \epsilon_{tcjobp} \tag{6}
\]
An important distinction is between mobile operating systems and desktop operating systems. There are less readily available privacy means for cookie management on the mobile web compared to desktop and consumer behavior in general tends to be different on mobile compared to desktop. For consistency with the privacy means substitution hypothesis, we would expect a larger difference in persistence on desktop compared to mobile whereas for consistency with the selective consent hypothesis we should expect no differences.

Table 7 displays the regression results with Windows as the omitted operating system that indicates that Android and iOS have no or weak increases in persistence for $k = 1, 2$ but appear to have an increase in persistence for $k = 3, 4$. This effect is significant and strongest for Android. Otherwise, the treatment effect is approximately the same across the different operating systems. Since there seems to be a weak difference between persistence on mobile and desktop this appears to favor the privacy means substitution effect, but does not provide conclusive evidence.

Notes: t-statistics are reported in parentheses. The standard errors for every regression are clustered at the website-country level. We aggregate every dependent variable to the website-country-product type-week level between weeks 16 and 26, including both weeks 16 and 26 (April 13th - June 29th). We restrict focus only to the most popular web browsers. The dependent variables in the regression are the consumer persistence measures for k = 1, 2, 3, 4, respectively. treated indicates whether the observation is associated with an EU website and past the GDPR implementation date. treated × browser indicates the heterogeneous treatment effect for the specified browser. The coefficients on browser indicate the estimated values for the browser fixed effect. The held-out browser is Google Chrome.

D Advertisement and Bidder Concentration

In this section we explore whether GDPR resulted in any changes in market concentration among advertisers. We utilize the standard definition for the concentration ratio and the HHI. $CR_{Ijt}$ is the concentration of impressions for the top $I$ out of $K$ advertisers on website $j$ at time $t$. Let $imp_{kjt}$ be the impressions of the $k$-th largest advertiser (according to impression share) on website $j$ at time $t$. Then, $CR_{Ijt} = \frac{\sum_{k=1}^{K} imp_{kjt}}{\sum_{k=1}^{K} imp_{kjt}}$. For a website $j$ and time $t$, the share of advertiser $k \in \{1, 2, ..., K\}$ is denoted by $s_k$. HHI is therefore defined as follows: $HHI_{jt} = \sum_{k=1}^{K} s_k^2$.

It is important to note that these measures rule out some demand driven changes but not all of them. In particular, advertisers could have churned without any changes in overall concentration and our exercise would not pick this up. However, this is the most plausible and easily measurable channel by which there could be demand-driven changes and so is our primary focus in determining whether the observed results are demand-driven. Table 12 shows the results of our main specification for $CR-1$, $CR-3$, $CR-5$, and $HHI$ as the outcome variables. There is a statistically significant increase in market concentration across each of these measures, though the effect size is not economically significant. Table 11 displays summary statistics for the various concentration measures and implies that the effect size, for instance, of the increase in market concentration for $CR-5$ is roughly 3%.

Figure 12 shows the time-varying treatment effect for the various market concentration measures, which all qualitatively follow the same pattern. The increase in market concentration occurs largely leading up until week 20 and remains relatively constant afterwards. However, the increase in average value of a consumer does not occur until week 25 and is a gradual, as opposed to a sudden, increase. Since the change in market concentration does not appear economically significant and the timing of the increase in concentration does not coincide with the increase
in the value of a consumer, this provides evidence that the increasing value of consumers is not driven by a change in the composition of advertisers.

E  Prediction Figures

Figure 13: Week by Week Treatment Effect (Average Predicted Probability and Class Proportion)
F Breakdown of MSE

In this section we further investigate the cause of the increase in MSE in our difference-in-differences analysis in section 6. In order to do so we utilize a standard decomposition for the MSE in the classification context and study the effects of GDPR on each component of the decomposition. The MSE for binary classification problems can be decomposed into a calibration and refinement component (DeGroot and Fienberg, 1983). The calibration component indicates the degree to which the estimated probabilities match the true class proportion. The refinement component indicates the usefulness of the prediction where a more refined prediction is one that is closer to certainty (i.e. closer to 0 or 1 with 0.5 being the most uncertain). Thus, a classifier with a good MSE is well-calibrated and more refined. This decomposition requires a discretization of the estimated probabilities into a series of $K$ bins.\footnote{Throughout this paper, when calculating the decomposed MSE we will primarily utilize equally spaced bins of size 0.01. Note that since the decomposition requires this discretization, the decomposed MSE and the standard MSE are not precisely the same quantities but are approximately the same.} For notation, $p_k$ denotes the $k$th estimated
probability bin, \( n_k \) denotes the number of probability estimates falling into the \( k \)th bin and \( \bar{o}_k \) denotes the true class proportion in the \( k \)th bin in the data. This allows us to rewrite (4) as:

\[
MSE_j = \frac{1}{\sum_{i \in I_j} |K_{ij}|} \sum_{k=1}^{K} n_k (p_k - \bar{o}_k)^2 + \frac{1}{\sum_{i \in I_j} |K_{ij}|} \sum_{k=1}^{K} n_k \bar{o}_k (1 - \bar{o}_k)
\]

(7)

calibration error                   refinement error

We run the same specification utilizing each component of the decomposition of the MSE as the outcome variable. These results are reported in Table 13. They indicate that both the refinement and calibration components increased after GDPR. Both of the components are approximately equally responsible for the increase in MSE with the calibration component being only slightly larger. The increase in calibration error is driven by the classifier’s lack of rapid adjustment to the post-GDPR consumer distribution leading the estimated class probabilities to no longer as closely match the empirical class probabilities. However, the increase in refinement error points to a partial adjustment since this increase is a result of the increased uncertainty in the predicted class (i.e. the class proportion moving closer to 0.5.).

Notes: t-statistics are reported in parentheses. The standard errors for every regression are clustered at the website-country level. We aggregate every dependent variable to the website-country-product type-week level between weeks 16 and 29, including both weeks 16 and 29 (April 13th - July 20th). The dependent variable in the regression reported in the first column is the calibration component of the MSE. The dependent variable in the regression reported in the second column is the refinement component of the MSE.
The Impact of Consumer Persistence and Data Scale on Prediction

The analysis in section 6 on the effect of GDPR on the firm’s ability to predict is limited by the data restrictions and the apparent lack of adjustment by its prediction algorithm to the post-GDPR environment. To fully understand the implications for prediction, therefore, we now take a different approach. Instead of asking how the firm’s prediction was actually impacted in the immediate aftermath, we now ask what would happen to predictive performance in the long run when the algorithm were fully adjusted.

As observed in section 4, GDPR reduces the number of consumers that the intermediary observes but remaining consumers are more persistently trackable. Our approach is to study how these two features—number of observed consumers and the persistence of observed consumers—impact the two measures of prediction performance cross-sectionally by comparing across websites differing in these two dimensions. We use a dataset aggregated at the website-product type-week level. We restrict attention to the pre-GDPR period between January 19th and April 6th. We rely again on the fact that the intermediary only utilizes the data from each individual website in order to train the model for that website. This ensures that predictions for each website are only responsive to the data size and persistence of that website.

We run the following regressions where the dependent variable, $\text{pred}_{tcjp}$ represents the prediction error of website $j$ in country $c$ for product type $p$ at time $t$. The fixed effects are the same as in the primary empirical specification and the standard errors are clustered at the website-country level, the same as with the previous specifications:

$$\text{pred}_{tcjp} = \beta \cdot \log(\text{Recorded Searches}) + \alpha_t + \delta_{jc} + \omega_p + \epsilon_{tcjop}$$ (8)

$$\text{pred}_{tcjp} = \beta \cdot \text{Consumer Persistence} + \alpha_t + \delta_{jc} + \omega_p + \epsilon_{tcjop}$$ (9)

Table 14 displays the OLS estimates of the regression relating total recorded searches on prediction error, using both the MSE and AUC as the dependent variables. We report the results of running the regressions with and without the website and website-country fixed effects, but our preferred specification is the one without the website and website-country fixed effects.\(^{41}\) This corresponds to the regression results in Columns (1) and (3) of Table 14. As expected, an increase in the total recorded searches increases AUC significantly and decreases MSE, albeit insignificantly. Recall that our point estimate of the magnitude of lost data from the GDPR was 10.7%. With this data loss, the magnitude of the predicted decline in prediction error is relatively small

\(^{41}\)The reason is that the website-country fixed effects soak up the variation in different dataset sizes across websites, even though understanding how this variation impacts prediction error is our main interest.
with a 10.7% decrease in recorded searches only leading to a 0.0007 decrease in AUC.\footnote{In reality the intermediary does not train its models only on data from the current week, but rather utilizing a sliding window of data that includes previous weeks. Table 15 shows the results for the same specification, but uses a sliding window total of recorded searches instead of the weekly total number of recorded searches, and shows that the point estimates do not change much when taking this into account.}

Table 16 displays the OLS estimates of the regression relating four week consumer persistence to prediction error, using both the MSE and AUC as the dependent variable. As before, we have regressions with and without website and website-country fixed effects, and focus primarily on the regressions without them. Recall that we previously found a 0.00505 increase in the four week persistence as a result of GDPR. Combined with the point estimates from Table 16, this implies an increase of 0.013 for AUC and a decrease of 0.007 for MSE.

Putting these two results together point to the fact that the decline in the overall scale of data should have little impact on predictability, but the change in the nature of the data towards more identifiable consumers should marginally improve prediction according to both AUC and MSE. However, this does not imply that the scale of data is unimportant which would run counter to standard statistical intuition; on the contrary, prediction ability improves substantially as the scale of data increases. Rather, the change in the scale of the data as a result of GDPR is not large enough to cause meaningful changes in prediction error in the long run. However, the increase in persistence as a result of GDPR should lead to an improvement in prediction capabilities in the long run.
